SUMMARY

In July of 1987 a grant under the "Financial Assistance for Mineral Exploration" program was awarded to Westar Mining Ltd., Greenhills Operations. The grant was used as partial funding of an exploration program designed to; a. Further identify and delineate low strip ratio high volatile reserves, b. Perform a preliminary investigation of 7 & 10 seam as a possible replacement for 1 seam in our standard metallurgical product.

During the program 5,497 meters of reverse circulation drilling were drilled with 40 holes completed. Eighteen holes were drilled for 10 seam or a combination of 7 and 10 seam. The remaining holes were drilled in the high vol. area.

Drilling density in the high vol. area is high enough to give sufficient information to complete the detailed mine planning. In the 10 seam south block enough information is now available to complete the preliminary mine planning. In the northern block 10 seam sufficient information has been generated to demonstrate the continuity of the seams but further work should be done before mine planning is started.

The general objectives of the program have been completed as outlined in the original proposal.

1.0 INTRODUCTION

1.1 Location

The project is located in the vicinity of the existing Greenhills mining operation with the target area divided into two blocks. The area lies approximately 12.5 kilometers north and 2.5 kilometers east of Elkford and 51 kilometers north of Sparwood. (See Index Map Figure 1.)

1.2 Access

A paved road connects Elkford to the Fording Coal surface mine. Access for contractors to the project area is from this road, via secondary logging roads, through the south end of Fording Coal's property. Access for Greenhills personnel working on the project was via exploration roads from the north end of the Greenhills Mine.

1.3 Topography, Climate and Vegetation

The topography of the area is the same as that of the Greenhills Mine. The area lies mainly along the crest of the Greenhills Ridge which has a very steep slope and is cut by several ephemeral streams which flow into the Elk River 850 metres below the ridge crest. Vegetation on the upper part of the west side is sparse consisting of mainly grasses, herbs, shrubs and a few stunted trees. Several ephemeral streams flow east from the ridge into Cataract Creek 450 metres below the ridge top. On the east side, the topography is less steep with several spurs projecting to the east. The east side of the ridge is mainly open as the result of clearcut logging with a few conifers remaining near the crest. On the south block vegetation on the east side of the ridge is similar to that on the west side, i.e. Grasses, herb and shrubs. The climate is the same as the Greenhills Mine area with generally cool Summers and Falls, rainy and wet Springs and cold Winters with moderate to high snowfalls.

1.4 Land Description and Ownership

During February of 1968, Westar Mining Ltd., then Kaiser Coal Ltd., acquired the coal rights to 43,725 hectares of coal-bearing lands from Crows Nest Industries Ltd. The Greenhills Mine exploration program area covers approximately 315 hectares in two blocks and was part of this acquisition. The larger block (270 hectares) is to the northeast and adjacent to the present Cougar North Pit. The smaller parcel lies just north of the present Eagle Pit and below the 16 Seam footwall, (See Index Map Figure 1). The property is located within Lot 1, District 4588 Plan, Kootenay District Certificate of Title 117880.

2.0 OBJECTIVE OF PRESENT PROGRAM

2.1 Greenhills Mine Overview

Westar's Greenhills Mine located northeast of Elkford produced 2.48 million tonnes of metallurgical coal and 650,000 tonnes of thermal coal in 1987 and present projections indicate that production will remain at this level for several years. The markets for both types of coal are improving but remain very competitive with the current excess supply expected to continue into the immediate future. Coal prices have declined every year for the last six years, eliminating some of the less cost-efficient producers. To remain competitive and maintain our market share, alternate means of increasing productivity and cost-efficiency, and developing new markets are continually under investigation. Optimizing the mine plan through the development of a superior geological model will help to accomplish this.

2.2 Objective

Two general targets were outlined at the commencement of the 1987 exploration program:

- (a) Shipment of high V.M. metallurgical coal in late 1986 and early 1987 indicated that long term contracts were available if sufficient mineable reserves could be identified. The strong demand that existed at that time has softened somewhat although good markets are still available. The 1986 program identified high V.M. reserves and the 1987 program was intended to generate information for detailed mine plans.
- (b) Because of geotechnical constraints imposed late in 1986 about 4 million tonnes of low volatile coal had to be removed from the 5-year mine plan. The low volatile component forms about 40% of our standard blend which represents about 90% of the metallurgical coal produced and sold by the Greenhills mine. Exploration was required on 7 and 10 Seams in order to identify replacement coals for the lower volatile component of the blend.

3. EXPLORATION WORK

- 3.1 Pre 1979 work in the project area was minimal. An access road was built in the early 70's and five rotary reverse circulation holes were drilled. In the mid 70's further bulldozer work for access and drillsites was completed and eleven core holes were drilled for structural and quality information.
- 3.2 Between 1980 and 1984, sixteen more rotary reverse circulation holes along with the associated cat work were completed using Greenhills' Schramm Reverse Circulation drill. This work was concentrated on the south and east sides of the present project area.
- 3.3 In 1985 another small program of twelve reverse circulation drillholes was undertaken with encouraging results. To carry out this program a contract drill rig and dozer were used.

- 3.4 In 1986 an extensive exploration program was carried out to identify high V.M. reserves. During this program approximately 12,000 metres of road was built using a contracted D8K dozer. Fifty-six CSR drillholes were completed for a total of 9,400 metres. To complete the drilling, two contract CSR drill rigs and our own Schramm reverse circulation drill were utilized.
- 3.5 During the late summer and fall of 1987 a drilling program was carried out with the aid of a F.A.M.E. grant from the Provincial Government of B.C. Approximately 7.5 Kilometers of new road and 46 drill sites were built utilizing a contracted D8K. During the program, forty 13 cm CSR (centre sample return) drill holes were completed. Thirty-four of these holes, for a total of 4,634 metres, were completed with the Greenhills Schramm T685D reverse circulation drill. The remaining five holes (863 metres) were completed by a contractor using Cyclone TH70 with a 600 cfm/250 psi compressor.

4. DRILLING, SAMPLING, ETC.

4.1 Drilling

The drilling was divided into two areas of concern; (a) Replacement coal for the low volatile component of the blend; (b) High V.M. metallurgical coal.

- (a) Drilling for replacement coal consisted of a preliminary exploration program to gather information mainly on 10 Seam with some holes going as deep as 7 Seam. Eighteen holes were drilled for this section of the program for a total of 2,540 metres. The average depth was 134 metres with a maximum of 250 metres.

(b) Drilling in the high volatile area was required, to resolve anomalies which existed, prior to developing the mine plan. Twenty-two holes for 2,760 metres of drilling was completed in this area. The average hole depth was 131 metres and the maximum was 248 metres.

All the drill holes started off at 130 mm or 140 mm in diameter and were reduced as required down to a minimum of 120 mm in increments of either 3 or 6 mm. All holes were started vertically and no deviations were run on any of the forty holes in this program. Table 1 lists the coordinates of all the holes drilled in the project area during the 1987 program. Maps 481-3 and 481-4 (in pocket) shows the location of all the holes drilled as well as all previously existing and new roads in the project area.

4.2 Sampling and Assaying

Assay work on all drill hole coal intercepts was performed by Westar's Central Laboratory in Sparwood, B.C. The procedures followed are shown in plates 1 and 2.

All coal zones were sampled in either five foot or one metre increments. These increments were then sent to the lab for analysis of ash and F.S.I. Lab results were then returned to the Geology Department and composites were determined based on these results. The incremental samples were combined by the lab to form composites to represent seam intervals. Composites were subjected to the standard tests as outlined in the procedures plus any optional tests which are required.

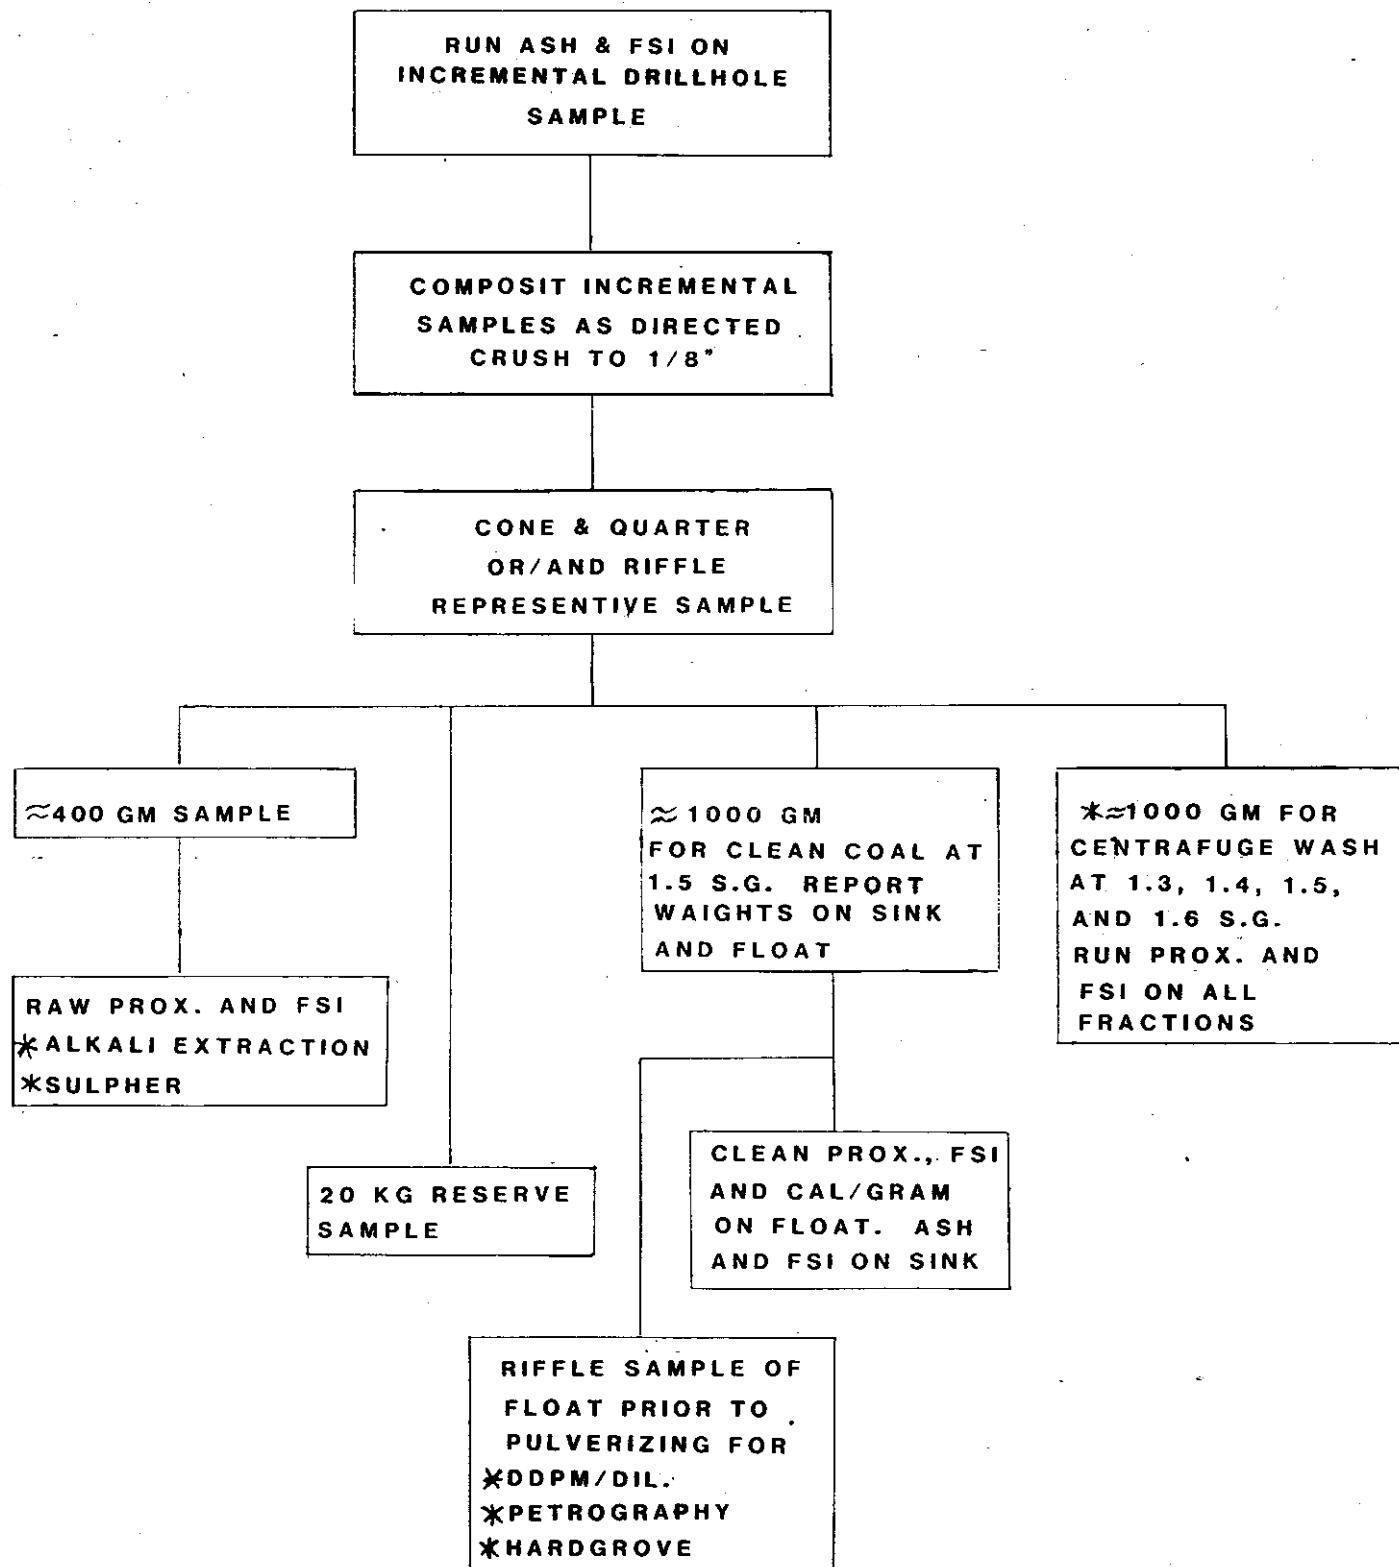

Table 2 gives a summary of the Quality by Seam for the major seams of interest and Appendix I gives the available raw data for the sampled coal intercepts encountered in the 1987 drilling program. Appendix 2 gives all available quality data by hole by seam within the general area of the Greenhills mine exploration area.

PROCEDURE C1-GH

NOTE: *Indicates optional test to be performed only on request.

PROCEDURE C2 -GH

NOTE: *Indicates optional test to be performed only on request.

4.3 Hole Logging

All the holes drilled in the 1986 program have been logged using a Model T450-E S.I.E. Gamma ray downhole logger. A reproduction of all the logs for the holes drilled during the 1987 Greenhills Mine Exploration program are included in Appendix 3. Because of manpower constraints, chip logs were not made and chips were not saved. Although it was realized that deviation logs would be useful for more accurate structural interpretation, they were not run at the time because of time and manpower constraints. Deviation surveys will be run during 1988 if time permits. Seam intercepts from the gamma logs were used in determining hanging wall depths and seam thicknesses for coal intervals.

5.0 GEOLOGY

5.1 General Geology

The project area lies within the top half of the Mist Mountain Formation which is the coal-bearing horizon of the Kootenay Group of the Upper Jurassic-Lower Cretaceous Era. The Upper Mist Mountain Formation is interpreted to have been deposited in an upper deltaic-plain or alluvial plain depositional environment. The predominant lithology is fine-grained sandstones, siltstones and mudstones interspersed with carbonaceous zones and coal seams. Coal seams vary from regionally continuous to very limited in lateral extent resulting in the amount of coal in the stratigraphic section varying greatly from place to place within the project area. The lower half of the Mist Mountain formation is a lower deltaic-plain and/or Barrier Bar type depositional environment. The lithology tends more toward the courser type sediments. Coals zones are not as abundant as in the upper Mist Mountain but tend to be more consistent and continuous. Plate 3 is a generalized stratigraphic column of the Mist Mountain Formation.

5.2 Structure

The major structure affecting the reserve area is the Greenhills syncline which is north-south trending and plunges gently to the north. The beds on the west side of the axis dip easterly up to 45° except in the vicinity of the axis where the structure has been complicated by drag folding, minor thrust faulting and late small scale normal faulting. The beds on the east limb dip steeply to the west and are cut off on the east by the Fording River normal fault which has a displacement of several hundred metres. The beds on the east limb have been structurally disturbed by numerous minor thrust and normal faults. Maps 481-3A and 481-4A (in pocket) illustrates the major structural features and the projected seam outcrops of 7, 10, 16, 20, 22 and 25 Seams in the project area. Cross-sections AA through VV which are included in the pocket, are drawn between holes and show the structural configurations of the coal seams in relation to the major structural features of the project area.

Also included in the pocket in the back are copies of computer-generated hangwall and isopac maps for 7, 10, 16, 20, 22 and 25 Seams. These are the same maps that were used to generate the reserve volumes.

6.0 ECONOMIC GEOLOGY

6.1 Seam Descriptions

The main thrust of this year's exploration was to delineate replacement coal for the low volatile component of our standard blend and to define the structure and quality of the high volatile area to the point where detailed mine planning can be done. The number of seams vary from drill hole to drill hole, however Seams 7, 10, 16, 20, 22 and 25 appear to be more or less continuous throughout the area under investigation.

6.1.1 7 Seam

Seven Seam is one of the major seams on which we have the least information. It appears that it is continuous from the south end of the Greenhills to the north property boundary. Thickness on 7 Seam varies from 7 to 14 metres and the seam lies 50 to 75 metres below 10 Seam. The insitu raw ash of 7 Seam is 18-22% and rock partings near the footwall and hangingwall are common. The seam has a dry ash free V.M. of approximtely 26% and is considered as replacement for the present low vol component of our present blend.

6.1.2 10 Seam

Ten Seam is 100 to 125 metres below 16 Seam. The seam attains thicknesses of 3 to 16 metres in the area north-east of Cougar North Pit. The average thickness in this area is around 9 metres. In the south block of the project area, 10 Seam splits into several seams of variable thickness. These seams occupy a zone of between 15 metres and 25 metres, the coal being 30% to 70% of the total zone with the percentage of coal decreasing from the south to the north. Ten Seam is a m.v.b. coal with dry ash-free V.M. of 27.5%. The raw ash of 10 Seam is 20% plus, however a good portion of this ash is in the form of small rock partings which are easily separated out by the breaker or wash plant.

6.1.3 16 and 16L Seams

These are a continuation of 16 and 16L Seams in the Cougar North development. 16 Seam is the most continuous of all the upper seams in the north dump area. The thickness is variable from 11 metres to 5 metres and is generally thinning to the north. These seams range in ash from 12% up to 30% with 16L nearly always being higher in raw ash than 16 Seam. These seams are borderline high vol with dry ash-free V.M.'s of 30% to 32%.

6.1.4 20 Seam

Twenty Seam varies between 0 and 7 metres thick and does not show any consistent thickness trends. It lies 30 to 50 metres above 16 Seam and sometimes occurs as split into an upper and lower seam. The seam(s) are generally quite clean with an ash of 14% to 20%. 20 Seam is the first seam in the section which consistently falls into the high vol classification of greater than 31% V.M. on air-dry mineral matter free basis (dmmf).

6.1.5 22 Seam

This is a zone rather than a single Seam and usually contains two or more seams of varying thickness over a 10-15 metre interval. Total coal in the zone can be as much as 6 to 8 metres. The zone lies 20 to 40 metres above 20 Seam on the west side of the syncline and only 5 to 20 metres above on the east side. Ash in the 22 seams varies from 8% up to 25% and V.M. in 22 Seam is about 33% on a dry mineral matter free basis (dmmf).

6.1.6 25 Seam

Seam 25-26 is located 20 to 40 metres above 22 Seam and is occasionally over 5 metres thick. In some areas this seam is quite dirty due to numerous rock splits which occur. Raw ash varies dramatically between 10% and 45% in direct relation to the number and thickness of the splits which occur. V.M. on d.m.m.f. is in the range of 34%.

6.1.7 Remaining Seams

Numerous other seams occur within the area under investigation. These seams vary in thickness from less than one metre to over seven metres. Above 16 Seam these seams are lenticular in configuration making coorelation difficult.

Below 16 Seam the seams tend to be more continuous and have a larger lateral extent. Seams 11 and 13 underlie 16 Seam virtually everywhere in the northern block, whereas these seams are absent from the section between 16 and 10 Seams in the south block. These seams form a part of the reserve base where they exceed 1.5 metres in thickness.

6.2 Quality

The quality of the seams vary considerably with respect to parameters such as raw proximate, washability characteristics, and reological tests. All the seams above 16 Seam, however, have one thing in common, on the basis of reflectance and clean V.M.'s they are classed as high volatile coals. The upper seams, that is 16 and up, have generally proven to be very easy coals to clean with difficulties ranging 10% to 20% at 1.55 S.G. and a clean ash of 6.5% to 7.5%. The exception which has been noted in the present mining operations is 20 Seam which gives a low yield when washed to a 7% ash. The seams below 16 Seam can be classified as medium volatile bituminous coals (m.v.b.). These coals are more difficult to wash than the upper seam coals with difficulties ranging from 20% to 35% at 1.55 S.G. and a clean ash of 7.5 to 9.0. Table 2 is a summation of the quality of the main seams encountered in the project area. Appendix 1 gives a summary listing of all the available quality of all the coals by hole and by seam for the past summer's program. Appendix 2 is a compendium of all the available quality data by hole by seam within the general area of the Greenhills Mine Exploration program.

Vehicles 1 pick-up	\$ 3,825	
	\$	
	\$ 3,825	\$ 3,825
Total Eligible Expenses		\$ 326,817

(b) For the following activities only 25% of total costs are eligible:

Tunneling, Drifting, Other Lateral Excavation, Shaft Sinking (25% of total expenses are eligible)		
m @ \$	= \$ × 25% = \$	
m @ \$	= \$ × 25% = \$	
	\$	\$

(c) TOTAL ELIGIBLE EXPENDITURES: \$ \$ 326,817

SUPPLEMENTARY INFORMATION: The following information is required in order to help us determine the contribution which mineral exploration activity makes to the economy, and relates to the utilization of B.C. vs. outside labour and services. Only figures directly attributable to the funded program should be included (approximate figures acceptable, but please be as accurate as possible).

(a) Employment, wages and salaries

Type	No. Employed		No. Person-days		Salaries/Wages Paid	
	B.C.	Outside	B.C.	Outside	B.C.	Outside
Prospectors					\$	\$
Linecutters						
Technicians	4		117		20,475	
General Labourers Samp. Prep.			204		40,800

TOTALS:	\$ 115,028	\$ 39,447

IMPACT OF FAME GRANT

(a) Please indicate what level of expansion of your project was attributable to receiving a FAME grant.

\$ 180,000 Including Grant

450 person/days employment.

(b) Please indicate what you feel to be the main achievement of this FAME funded program.

To advance the mine planning stage of the project by a year and to confirm the continuity of the 7 and 10 seam replace coals for continuation of standard blend production.

STATEMENT OF QUALIFICATIONS

L. B. SAMUELSON

B.Sc. Geological Engineering, 1964
Michigan Tech University
Houghton, Michigan

Member of The Association of Professional
Engineers of British Columbia 1979

18 years of practical experience in all aspects of
coal exploration and development including:

- Mapping and structural interpretation.
- Design and execution of exploration programs for
coal entailing mapping, drilling, tunnelling and
trenching.
- Pit geology quality control.
- Special studies related to coal development and
quality.
- Mine planning and pit design.
