February 26, 1991

Coal Administrator
Ministry of Energy, Mines and
Petroleum Resources
525 Superior Street, Room 17
Victoria, B.C.
V8V 1X4

ATTENTION: MS. KIM STONE/PAUL HAGEN

Please find attached two copies of the documentation required from Crows Nest Resources Ltd. for our application to convert five coal licenses to a lease. Also attached are cheques covering the application fee and the prescribed rent as per Sections 24 (2) (a) and 24 (2) (b) of the Coal Act.

Development activities for the pit area contained within the lease applied for are scheduled for start up May 1, 1991. Permitting and licensing of the plans has been initiated with the Mines Department and the appropriate Environmental agencies. Due to the tight time constraints your speedy attention to this lease application would be appreciated. To facilitate your circulation of this document, two (2) copies have been enclosed.

Any questions regarding this application should be directed to the undersigned.

Yours truly,

CROWS NEST RESOURCES LTD.

R. Williams

1.0 BACKGROUND INFORMATION

1.1 Corporate Structure

Crows Nest Resources Limited (C.N.R.L.) was incorporated in 1978 to manage the development of the consolidated coal holdings of Shell Canada Resources Ltd. (SCRL) and Crows Nest Industries Limited (CNI) following the acquisition of CNI by SCRL. The Line Creek property was part of the CNI acquisition. CNRL is structured as a wholly-owned subsidiary of SCRL but operates as an independent business unit of Shell Canada. It carries out its function with four main departments: Mining, Exploration, Marketing and Planning and Administration.

1.2 Land Tenure

Enclosure 1: Index Map (1:50,000)

The Group #330 coal licenses have been held in good standing since 1975; initially by Crows Nest Industries Ltd. and subsequently by Shell Canada Ltd. Exploration work has been done on various portions of Group #330. Listed below are the monies spent in each year on each project.

PROJECT	1978	1979	1980	1981	1989	1990	TOTAL TO DATE
MT. MICHAEL			$39,887	$243,429			$283,316
EWIN PASS	$90,653	$250,921	$503,514	$494,214			$1,339,302
M.S.A.N.					$51,644	$198,000	$249,644
							$1,872,262

1.3 Site Description

Enclosure 1: Index Map (1:50,000)

The Mine Services Area North (M.S.A.N.) coal licences are located 14 kilometres southeast of Elkford, British Columbia, in the front ranges of the Rocky Mountains in southeastern British Columbia. These licences consist of CL 291, 288, 289, 287 and 1300 are centred at approximately:

Latitude 49° 59' North

Longitude 114° 45' West

The proposed pit and dump areas lie partially within Coal Lease #4. The balance lies immediately adjacent to the north, within portions of the above named coal licenses, which belong to Group 330 in the Central Block area. The pit, dumps and roads associated with this proposal are on Crown land, and logging for development is covered under License To Cut YN571, which encompasses all of the Line Creek mine development activities.

The M.S.A.N. area upon which the exploration has been focused, extends from the Line Creek valley bottom up onto the east-facing slope of Mount Michael. The elevation varies from 1580 metres - 2475 metres (ASL). Natural outcroppings of resistant sandstone units are fairly abundant and the Mist Mountain Formation/Morrissey Formation contact can be traced over most of the property. Coal seam exposures are restricted to road cuts and hand trenches.

The proposed mining area is a steep (15° - 50°) hillside, mostly timbered, that toes out onto a flat valley bottom. The Line Creek headwaters in this area experience seasonal intermittent flows, and there is no development other than evidence of past logging activity upstream of the proposed mine site. Mining activity is within a trap line area owned by a local trapper, and within an area easily accessible to recreational users seasonally.

Because of the proximity, the proposed lease area experiences essentially the same weather and climate regime as the adjacent developments within Coal Lease #4. Steepness of the terrain precludes agricultural capability within the area. Generally, terrain steepness and timber quality make logging and management of the site for timber production uneconomical.

At the present time, vehicular access is via; mine service roads in the valley-bottom north of the Mine Services Building, the 1989 exploration road into the M.S.A.N. area and the Ewin Pass Road.

1.4 Coal Preparation Facilities

The Line Creek operation features independent coal processing facilities for thermal coal and metallurgical coal. This process separation increases operating flexibility,

maximizes product recovery and minimizes conflicts in shipping schedules.

Raw coal blending and storage is accomplished in the preparation process by the use of five 5,000 tonne capacity enclosed concrete silos. Each silo is a predetermined, dedicated storage for one particular seam or combination of seams. In addition, three of the five silos are reserved for metallurgical coal, one is for thermal coal only, and the fifth may be used for either coal type.

Thermal and metallurgical coals are usually processed in separate plant facilities. With appropriate feeds, the plants are capable of producing up to 2.0 million tonnes per year of clean thermal coal and 2.25 million tonnes per year of clean metallurgical coal. The metallurgical coal preparation process design is typical of the type required to process Western Canadian coal. It therefore emphasizes fine coal cleaning.

The metallurgical plant features a combination of heavy medium cyclones, water cyclones and flotation, followed by thermal drying to achieve specified moisture content.

In the thermal plant, raw coal is screened, then cleaned in a heavy medium bath. Drying is not required.

Current run-of-mine coal production has a reduced proportion of thermal coal, a portion of which is treated in the metallurgical plant, resulting in an effective metallurgical plant capacity of 2.0 million clean tonnes per year over the ten year plan. Under these conditions, the thermal plant capacity is significantly underutilized.

Unit train loading utilizes computer control with cars loaded at a rate of 3,000 tonnes per hour. A nominal unit train consists of 110 cars, each holding 94 tonnes of clean coal.

1.5 Manpower

Currently, CNRL has about 470 employees, of whom 457 are at Line Creek while the remainder are based in Calgary. Under the current proposal for the M.S.A.N. Pit and the mining activity scheduled on the Lease 4 Pits, no change in manpower is required.

1.6 Union Representation

The hourly employees of Line Creek Mine (mine and plant operators, maintenance and warehouse personnel) have been represented by the International Union of Operating Engineers, Local 115C since the company began operating in 1981.

Currently there is a three year collective agreement in effect which expires May 31, 1992.

1.7 Sales Contracts

The following data summarizes the current sales contracts for all coal presently being produced from the Line Creek Mine. The proposed M.S.A.N. Pit would release coal that would be slotted into these contracts where appropriate.

METALLURGICAL COAL

CUSTOMER	VOLUME (1,000 metric t/y)	CONTRACT DURATION
1. Grouping of 10 Japanese Steel Mills	1,016 +/- 10%	15 yrs. April, 1983 to March 31, 1998
2. Ssangyong Corp. for resale to Pohang Iron and Steel Co. (Korea)	200 +/- 10%	5 yrs., April 1, 1988 to March 31, 1993
3. British Steel	165 + 55 option +/1 10%	3 yrs., April 1, 1990 to March 31, 1993 extendable
4. Massey Coal for resale to Inland Steel	336 +/- 15%	3 yrs., April 1, 1990 to March 31, 1993 extendable
5. Massey Coal for resale to USX	220 +/- 10%	I yr., Jan. 1, 1991 to Dec. 31, 1991 Purchase Order Term agreement under negotiations

THERMAL COAL

	Korea Electric		
1.	Samchonpo Power Plant	350 +/- 10%	Evergreen, reviewable every 5 years. Started fiscal 1982.
2.	Poryong Power Plant	400 +/- 10%	Evergreen, reviewable every 10 years. Started CY 1983.
3.	Honam Power Plant	400 +/- 10%	Evergreen, reviewable every 9 years.. Started CY 1985

2.0 GEOLOGY

2.1 Summary of Work Done

Between 1975 and 1976 Crows Nest Industries Ltd. built the Ewin Pass access road, mapped the Mt. Michael and Ewin Pass areas at a scale of 1:12,000 and drilled nine reverse-circulation rotary holes in the Ewin Pass area.

In 1978 Shell Canada again mapped the area at scales of 1:24,000 and 1:12,000. Some coal seams were hand-trenched.

In 1979 additional detailed scale (1:2,000) mapping was done and 150 metres of trenching and three adits were driven for bulk samples in the Ewin Pass area to the north.

Additional drilling, trenching and sampling was done in Ewin Pass during 1980 and 1981. Six diamond holes and five rotary holes were drilled, sampled and geophysically logged. Some of this data will be extrapolated into the M.S.A.N. area as the geological interpretation develops.

The 1981 Mount Michael Geological Report by A. White covered the north central area of Mount Michael and some of his findings were extrapolated into the Mine Services Area North Project area. Physical work included extensive mapping and hand trenching.

The 1989 program on M.S.A.N., as reported on by Sharma, consisted of geological mapping (1:2000), four rotary drill holes, backhoe trenching and road upgrading in a small portion of the M.S.A.N. area 1.4 km north of the Mine Services Building.

Work done in 1990 on M.S.A.N. included 370 metres of road construction, geological mapping (1:2000 scale), 190 metres of backhoe trenching, 4279 metres of CSR rotary drilling in 23 holes and one bulk sample site (Test Pit).

2.2 *Regional Stratigraphy and Structure*

Enclosure 2: Table of Formations

Enclosure 3: Regional Geological Map (1:20,000)

The Kootenay Group has been subdivided into three formations; the lower Morrissey Formation, consisting of Moose Mountain and Weary Ridge Members; the Mist Mountain Formation, and the uppermost Elk Formation.

The Mist Mountain Formation of the Kootenay Group of Upper Jurassic-Lower Cretaceous age is the main coal-bearing sequence in southeastern British Columbia. It is a thick sequence of clastic sediments representing delta progradation over marine shales, siltstones and sandstones of the Jurassic Fernie Formation.

The ***Moose Mountain Member*** is a resistant, generally cliff forming unit comprised of massive, medium to coarse grained, medium gray weathering sandstone. There are commonly two coal horizons within this sandstone, but their small thickness (rarely over one metre) and the overlying massive sandstone make them unattractive for economic consideration. The distinctive nature and prominence of this unit makes it an easily traceable marker horizon throughout the Crows Nest Coal Field of southeastern British Columbia.

The ***Mist Mountain Formation*** is the main coal bearing unit of the Kootenay Group. It overlies conformably but abruptly the Moose Mountain Member.

It is comprised of a generally recessive, interbedded sequence of brownish tinted sandstones, gray to brown siltstones, gray and black shales, gray mudstones and coal seams. In the Elk Coal Field this formation ranges in thickness between 400 metres and 660 metres. The coal seams attain a thickness of up to 10 metres and a lateral extent of several kilometres.

The ***Elk Formation*** lies conformably but abruptly over the Mist Mountain Formation. It consists of an interbedded sequence of cliff forming sandstones, shales and siltstones and thin (less than one metre), sporadic coal seams.

Coal bearing Mist Mountain Formation occurrences in the front ranges of southeast British Columbia are preserved in north/south trending synclines referred to as the Crowsnest Coal Field. The structure within the synclines is complicated to varying degrees by thrust faults, and to a lesser extent, normal faults.

The Crowsnest Coal Field can be subdivided into three coal bearing areas. From south to north they are the Flathead Coal Field, the Fernie Coal Field and the Upper Elk Coal Field (where this project area is located).

Upper Elk Coal Field

The Upper Elk Coal Field is an elongate basin composed of two major synclines (Greenhills and Alexander Creek) separated by an anticline and the northern extension of the Erickson Normal Fault. Line Creek is located at the southern end of the northerly plunging Alexander Creek syncline. The Ewin Thrust Fault causes a repeat of the east limb of this syncline. The Mine Services Area North Project is located in the footwall of this thrust fault.

2.3 Mine Services Area North Stratigraphy and Structure

Enclosure 4: Typical Stratigraphic Sections

Enclosure 5: Geology + Access Map (1:10,000)

Enclosure 6: Geological Cross-Sections (1:2,000) - 7

The Mine Services Area North (M.S.A.N.) project covers an area under the Line Creek valley bottom and up onto the east-facing slope of Mt. Michael. The west-dipping Moose Mountain Member outcrops along almost the entire length of the project, with bedding attitudes ranging from 45° to 60° west. Up section, the bulk of the interesting coal occurs in the lower 100 metres to 250 metres of the Mist Mountain Formation. There are six zones containing mineable seams, with individual seams ranging in thickness from 1.0 metres to 11.0 metres. The coal seam nomenclature has been extrapolated from the Line Creek Pit and Ewin Pass areas into this project. Stratigraphic changes are evident along the strike from south to north. As well as seam changes within zones, complete zones move up and down in the stratigraphic section or appear to be replaced completely by major sandstone units. The geophysical log signature of the seams are consistent enough to allow relatively easy correlation throughout the project and into the adjacent Ewin Pass data to the north.

Correlation of the drill hole geophysical logs also shows ample evidence of a number of west-dipping, low angle thrust faults which affect both the Mist Mountain Formation and the Moose Mountain Member. Seam repeats are common. Attempts have been made to correlate these faults from one cross-section to the next, but more mapping and drilling is needed to properly interpret these structures. Displacement

on these faults ranges up to 20 metres vertically and 100 metres horizontally.

2.4 *Coal Quality*

Enclosure 7: Increment Quality Data

Enclosure 8: Composite Quality Data

Enclosure 9: Loring Quality Data

Enclosure 10: Petrographic Data

Enclosure 11: Test Pit Quality Data

In 1990 coal samples for analyses were obtained from reverse-circulation rotary drill holes, the backhoe trench and the test pit. A variety of tests were done on these samples by the Crows Nest Resources Ltd.'s lab, Loring Laboratories Ltd., and David E. Pearson and Associates Ltd. All of the data is included in the above enclosures, but as of yet no summary of the data on a seam-by-seam basis is available. The following comments are preliminary but serve to give some idea of the basic quality:

- Based on CSR drill hole data
  - raw ash varies from 15% - 35%
  - volatiles (at 1.6 S.G.) are in the 21 - 22% range
  - sulphur (at 1.6 s.g.) is low (0.3 - 0.5%)
  - RoMax (at 1.6 S.G.) ranges from 1.21 - 1.29
  - Calorific values range from 6200 - 7800 Kcal/kg
- There is evidence of "layering" within seams of "Met." and "Thermal" coal (based on raw FSI values). The reason for this layering has not yet been tied to either

oxidation or petrography. Some of these seams may be potential candidates for selective mining in order to optimize the reserves.

3.0 MINING PROGRAM

Enclosure 12: Mine Plans (1:2,000) - 3

Enclosure 13: Mine Cross Sections (1:2,000) - 3

3.1 Description of Mine and Access

The Mine Services Area North (M.S.A.N.) Pit is located approximately 600 metres northeast of Line Creek Mine Services Building. The pit will be developed to maintain the current coal feed to the existing plant.

The M.S.A.N. Pit will be developed as a conventional truck shovel operation. The pit has been designed with a 47.5° overall wall angle (Piteau Report PA-019). Total material removed is 5.0 million tonnes of coal and 15.1 million BCM's of waste material.

Road access to the M.S.A.N. Pit area is from behind the Mine Services Building. Initial upgrading of the road is to 13 metres at 12% for the first 450 metres. The second portion of the road is built at nine metres in width and grades varying between 7 and 11%. The 13 metre road width conforms to the Mines Act for a two way road when running a P-12 equivalent (4.5 metre width), and the nine metre road with pull outs conforms to the Mines Act for single lane traffic.

3.2 Surface Development

To date surface development has been in upgrading the existing road and removing a bulk sample.

Projected development over the next five years is to upgrade the existing road for two lane traffic, and progress with the road up to the apex of the pit. Development in the first year is a small pit that will be utilized to determine an optimum overall wall angle (Enclosure 12: Mine Plans - Proposed Test Pit). Development of the road will continue in the following year along with waste removal from the north end of the pit.

By year five the M.S.A.N. Pit will be half finished, with the 1950, 1900, 1850 and 1800 dumps completed, and the 1770 dump half completed (Enclosure 12: Mine Plans - Mid-Life Pit Plan).

The final five years of mining will concentrate on developing the south end of the pit. The 1770, 1740, 1720 and 1690 dumps are built into the Line Creek Valley and a dump at 1810 backfills the north end of the pit (Enclosure 12: Mine Plans - Ultimate Pit).

3.3 Pit Slope Design for M.S.A.N. Pit

The conditions of steep topography and bedding dipping 35° - 60° into the hillside have shaped a pit that daylights to the east and has a single highwall on its west side running parallel to topography and the strike of the bedding. The endwalls have been created naturally by steep gullies cut into the hillside.

The configuration of the highwall is very similar to the east hanging wall of the original North Line Creek pit. A slope stability analysis of this latter wall was completed by Piteau Assoc. in January 1986. Their recommendations have been followed for the preliminary design of the M.S.A.N. pit. Using 12 metre benches, a 10 metre berm is left every other bench, for an overall slope angle of 47.5°. The failure modes considered to control bench stability are stepping wedge and stepped plane failures. Backbreak is anticipated to be high and controlled blasting should be utilized.

Trial slopes or slope documentation will be used to evaluate and update the slope design on an ongoing basis.

3.4 Coal Reserves

In the proposed M.S.A.N. Pit, the calculated waste and coal volumes are as follows:

Waste:	15,132,000 BCM
Coal:	4,859,700 ROM tonnes
Strip Ratio:	3.11:1

Factored into these numbers are a 3% rehandle, 20% coal loss and a coal specific gravity of 1.5. For planning purposes, 75% of these reserves are considered to be metallurgical coal and 25% are thermal coal. The thermal coal is composed of near-

surface oxidized metallurgical coal and the "thermal" portion of the layered seams as referred to in section 2.4.

3.5 Waste Disposal

Waste disposal from the pit will comprise eight dumps that wrap around to the north and one dump that backfills the north end of the proposed pit. The wrap around dumps have been analyzed by Piteau and Associates. Disposal of soils and overburden would be placed in the dumps, these would not constitute large volumes because of the nature of the topography.

3.6 Water Management

A surface water management plan has been prepared to achieve the following objectives:

(1) Maintain water quality in Line Creek to comply with Waste Management Branch permit objectives during mine development.

(2) Separate all potentially sedimented tributaries and surface water for abatement prior to discharge into Line Creek during mine development.

(3) Design all hydraulic control, conveyance and treatment structures to handle expected flows (minimum one in 10 year flow).

Considerations for water management and drainage control related to the M.S.A.N. development deal with the following areas:

1. Mine Aocess Road Runoff

2. Tributaries of Line Creek

3. Line Creek

4. Settling Pond/Sediment Traps

3.6.1 Mine Access Road Runoff

Runoff from the mine access road will be directed into a ditch on the inside of the road, and thus carried downhill to the Mine Services Area and ultimately into Ponds 5 and 6. The ditch will be approximately 1.5 metres wide and 0.5 metres deep.

3.6.2 Tributaries of Line Creek

Three small creeks flow in steep gullies located across the south, middle and north portions of the site. Whereas, the north gully flows year round into Line

Creek, the flow in the middle and south gullies disappears into the alluvium and coarse colluvium of the Line Creek flood plain, indicating the minor nature of the flows in these creeks.

The south and middle gullies will be intercepted by the pit. The north gully serves as the site for the initial waste dump. The expected flow rates in all the gullies is low, but in order to ensure that the waste dump will convey the surface flows, the dump will be constructed within the gullies using select, competent, coarse-grained waste rock.

Sediment control will be maintained by directing the flow from these creeks into a ditch leading to a settling pond, which will be constructed immediately downstream from the mining area. It is anticipated that much of the flow will infiltrate to ground prior to reaching the pond.

3.6.3 Line Creek

Sedimented runoff from the mining area will be kept away from Line Creek by construction of a protective berm (as outlined in the report from Piteau Engineering addressing the stability evaluation of the proposed waste dump), and an associated ditch on the inside of the berm.

A short section of Line Creek will have to be diverted but the stream gradient will not change.

3.6.4 Settling Ponds and Sediment Traps

Baffle dykes may be placed at regular intervals across the ditch in the valley floor, in order to create small sediment traps, and minimize the sediment entering the settling pond. This will allow the maximum area for infiltration within the pond and thus likely eliminate any direct discharge into Line Creek.

Should the need arise, there is an opportunity for further treatment of runoff from the mining area. A longer section of Line Creek could be relocated to the east side of the valley, thus creating space for additional settling ponds.

3.6.5 Groundwater

This has also been addressed in the report noted above from Piteau Engineering.

4.0 IMPACTS AND MANAGEMENT

Enclosure 12: Mine Plans - Ultimate Pit

Enclosure 13: Mine Cross Sections

Enclosure 14: Wildlife Habitat Units

4.1 Wildlife

Approximately 80% of the nearly 100 ha. constituting the proposed pit/waste dump area is Class 4 summer range for bighorn sheep, and Class 3 summer range for elk, moose and mule deer. Habitat capability is restricted by steep slopes and high snowfall. The area contains several avalanche tracks, which contribute to high habitat diversity. Approximately 15% of the area of potential disturbance is Class 3 summer range for bighorn sheep, elk, moose and mule deer, limited by steep slopes, avalanche tracks, and high snowfall. The remaining 5% of the area is Class 4 summer range for moose, bighorn sheep and elk, and Class 3 summer range for mule deer. This area is sub-alpine meadow with upland forest soils and receives high snowfall. (Enclosure 14)

According to Demarchi, et al 1983 "Wildlife Capability Classification for British Columbia: An Ecological (Biophysical) Approach For Ungulates", winter range availability is usually the limiting factor for ungulate populations. There is an area of Class 3 moose winter range in the valley bottom adjacent to the proposed development, but mining activity will not encroach on it. Class 3 moose winter range has moderate capability, and can support 1.6-3.0 animals per square

kilometre per year under optimum conditions, therefore every effort will be made to minimize encroachment.

Class 3 and 4 summer range have moderate to low capabilities respectively and can support 0.4 to 3.0 animals of any one species listed per square kilometre per year. The proposed pit and dump development encompasses approximately one square kilometre, all of which is summer range, not generally considered limiting. It is anticipated that bighorn sheep utilizing the area irregularly throughout the spring, summer and fall will continue to do so as mining progresses, as has been the experience with Line Ridge mining development to date. Research indicates that moose are highly tolerant to loud noises and mining machinery activity as long as they are able to withdraw from it at will, and are expected to continue to use the adjacent Class 3 winter range when not limited by ecological factors like high snowfall. Elk and deer are expected to avoid the active mining area during development, but will benefit from reclamation efforts. Mining will displace approximately 100 ha. of summer range in the short term, which will be replaced by reclamation over the life of the mine.

Rehabilitation of the site will involve establishment of vegetation on resloped waste dumps to replace wildlife habitat capabilities temporarily displaced by mine development. The pit and associated waste dumps cover

approximately 100 ha., of which approximately 58 ha. will be re-vegetated to grasses, shrubs and conifers at abandonment. Planting highly productive agronomic grasses and legumes has been demonstrated in the Elk Valley to significantly increase the carrying capacity of some habitat types. Where summer range is being replaced, successful reclamation is expected to replace enough range to support the number of animals as were previously supported.

Site restoration will be ongoing, commencing with reclamation of early construction disturbances and continuing until all waste dump areas have been successfully re-vegetated. Detailed annual reclamation plans will be forecast in the appropriate Reclamation Permit reports submitted annually to the Head of Reclamation, Ministry of Energy, Mines and Petroleum Resources. The company will regularly monitor reclamation success to ensure that end land-use objectives (re-establishment of wildlife habitat) are being met.

4.2 Fisheries

Line Creek in the lower vicinity of the proposed development is described by B.C. Research (Stage II Environmental Study of the Line Creek Project, 1977) as "narrow, shallow and straight with few pools". Average gradient is 1.7%, and pool value is rated as Class 2 (depth approximately 2 feet and length greater than average channel width). Swift, straight, thickly

vegetated riffle areas are common. The presence of cutthroat trout and bull trout are probable but unconfirmed. In the upper stream reaches adjacent to the planned pit, Line Creek flows are intermittent, flowing underground in places. No fish populations are expected to persist in this area.

A toe berm and collector ditch between the mine development and Line Creek will be constructed to maintain water quality and channel integrity in the stream, and protect the riparian habitat which constitutes a portion of the Class 3 winter range for moose. A fisheries mitigation program to offset the loss of fish populations displaced by the rock drain in Line Creek upstream of the confluence with South Line Creek has already been implemented. Additional work to finalize the project will be undertaken in 1991, and will involve riprap placement on Line Creek and planting of willow clumps within the South Line Creek diversion channel. A monitoring program is ongoing to ascertain that the fisheries mitigation work is effective, and maintenance-free.

4.3 Recreation/Trapping

Vehicle access to the upper Line Creek valley is available to hunters and other recreationists via summer road from the Grave Lake area. Winter access is also available to snowmobiles over this same route, which skirts active mining areas to ensure public and worker safety. Development associated with the proposed mine will encroach on a

portion of the access road to the upper valley, and the company will ensure that access is maintained to those areas, possibly through construction of a short bypass road. A portion of the waste dump development may impinge on a trapline and cabin owned by a local trapper. To eliminate possible safety hazards associated with waste dump construction, the company will undertake to develop an action plan that will re-establish the trapper's facilities in an area not subject to future mining disturbance.

4.4 Archaeological/Historic Resources

Prior to development of the Line Creek Mine, a Heritage Resource Assessment was completed in 1976, which investigated the Line Creek/Ewin Pass area for evidence of historic heritage sites. A four man survey team conducted archaeological reconnaissance for a six week period, and identified sites in the lower Line Creek canyon area, as well as evidence of prehistoric cultural deposits at the summit of the west passage of Ewin Pass. The report does not document the existence of cultural sites in the area enclosed by this proposal. (Choquette, 1976)

4.5 Nitrogen Export

Ferguson and Leask (1988) developed a procedure for forecasting nitrogen export from Coal Mines as a function of type and quantity of explosives used.

For mines using ANFO, annual nitrogen export was 0.2% of the nitrogen contained in the ANFO, 98% of which showed up as an increase in nitrate values in receiving waters. ANFO is considered to be 33% N by weight. At a powder factor of 0.47 (kg ANFO per BCM of waste rock), it takes 705,000 kg of ANFO to produce the 1,500,000 BCM of waste rock annually for this pit development, which equates to a nitrogen content of 232,650 kg. The annual nitrogen release forecast by the Ferguson and Leask (1988) method would be 465 kg.

Nanuk (1988) used measured concentrations of nitrate, nitrite and total ammonia from Jan. 1983 to Dec. 1988 on Line Creek to calculate the distribution of loading on a monthly basis as a percentage of annual load. Flows in Line Creek downstream of the proposed development are related to measured flows at the mouth using a ratio of drainage areas of the two sites. The drainage areas are:

(a)	Line Creek at mouth	138 km^2
(b)	Line Creek U/S proposed pit	30.5 km^2

Using this ratio, flows in Line Creek upstream of the location of the proposed development are 22% of flows measured at the mouth.

The total potential annual nitrogen export from the development is apportioned over the year according to the

monthly percentages developed in Nanuk Engineering 1989, producing the following total monthly increases:

MONTH	PERCENT OF YEARLY TOTAL OF NITROGEN ADDITION	NITROGEN EXPORT FROM PROPOSED DEVELOPMENT (KG)
January	5.4	25.1
February	3.8	17.7

TOTAL	**100%**	**465.0**

Loading is calculated by apply the monthly nitrogen available for export to the average minimum daily flow on Line Creek at the proposed development site. Flows from the drainage area upstream of the site are calculated, and potential increases in nitrogen loading are as follows:

MONTH	AVERAGE MINIMUM DAILY FLOW (M^3/SEC)	TOTAL DAILY NITROGEN INCREASE (KG)	CHANGE IN CONCENTRATION OF NITROGEN COMPOUNDS (MG/L)
January	.0869	.8097	0.108
February	.0867	.632	0.084
March	.0899	.4645	0.059
April	.1096	1.937	0.205
May	.4129	2.671	0.075
June	.964	2.96	0.036
July	.4066	1.245	0.035
August	.2673	1.11	0.048
September	.2112	.993	0.054
October	.1797	1.2	0.077
November	.1223	.65	0.061
December	.0968	.6	0.072

Of these nitrogen compound increases due to export from blasting, Nanuk (1989) suggests that the inorganic nitrogen load is 87% nitrate-N, 11% ammonia-N and 2% nitrite-N.

Adding these values to average nitrogen concentrations just downstream of the proposed development at water sampling station 0200335 represents an estimate of expected water quality as a result of ANFO use during mining. The recorded values for nitrogen at station 0200335 represent nitrate ***plus*** nitrite ***plus*** ammonia averaged by month over a

five year sampling program, 1983 - 1988 and presented in Nanuk (1989).

MONTH	AVERAGE RECORDED N CONCENTRATION AT STN. 0200335 (MG/L)	EXPECTED N CONCENTRATION AT STN. 0200335 AFTER DEVELOPMENT (MG/L)
January	0.188	0.296
February	0.153	0.237
March	0.305	0.364
April	0.171	0.376
May	0.043	0.118
June	0.097	0.133
July	0.047	0.082
August	0.058	0.106
September	0.064	0.118
October	0.115	0.192
November	0.107	0.168
December	0.099	0.171

Nanuk (1989) states that leaching of explosive residue from the waste rock will result from surface runoff and vertical percolation of precipitation, and that these mechanisms are assumed to export nitrogen over a longer time frame than within the same year the waste is placed in the dump.

4.6 Reclamation

The objective of project reclamation will be to re-establish wildlife habitat values similar to those that existed prior to mining. Reclamation at Line Creek involves the rehabilitation of mining disturbances such that a diverse, effective and self-sustaining mosaic of native and agronomic vegetation species and other abiotic topography features such as rock piles, snags, cracks, ledges, holes and surface undulations are provided in a combination suitable as wildlife habitat. The aim is to provide habitat which is compatible with the needs of elk and Rocky Mountain Bighorn Sheep during spring, summer, and early fall, the period of potential use by these species on Line Ridge. These two species are common to the area both prior to and during the mining operation, and are therefore the target species for C.N.R.L. reclamation efforts (B.C. Research 1977, TAESCO 1982, TAESCO 1983). By improving the habitat for a key wildlife species, it is expected that other wildlife species will benefit as well, since the complex of wildlife species within a given plant community generally have similar habitat requirements (Green & Yonge, 1984). Waste dump slope angles will be reduced as required to ensure stability for vegetation re-establishment. Operational mine planning will incorporate measures to salvage till/topsoil where feasible. The material will be stockpiled on waste dump platforms, then spread after resloping to accelerate vegetation re-establishment. Ongoing research at the Line Creek mine has identified an

effective mix of grasses and legumes that readily provide vegetative cover on reclaimed waste dump slopes, as well as forage for ungulates using the area. Reclamation techniques will be incorporated to develop topography features capable of providing habitat diversity, and will follow the guidelines established in the Reclamation Plan for Reclamation Permit C-129. It is the company's intention to keep reclamation following closely behind mining to minimize the amount of area that is under disturbance at any one time. The final mine configuration after reclamation is illustrated in Enclosure 12: Mine Plan - Ultimate Pit and associated cross sections.

Backfilling will cover in a portion of the pit area, and these dumps within the pit will also be subject to reclamation similar to the out-of-pit dumps. Where backfilling is not feasible, a depression will remain that will eventually partially fill with water to as yet unknown recovery levels. In-pit pond development will be monitored to determine the potential for establishment of willow or other shoreline vegetation as forage for moose in the area. As well, the potential for a pond fishery will be investigated.

4.7 Logging

Merchantable timber will be removed from the site prior to development.

5.0 COAL QUALITY

Enclosure 9:	Increment Quality Data
Enclosure 10:	Composite Quality Data
Enclosure 11:	Loring Quality Data
Enclosure 12:	Petrographic Data
Enclosure 13:	Test Pit Quality Data

In 1990 coal samples for analyses were obtained from reverse-circulation rotary drill holes, the backhoe trench and the test pit. A variety of tests were done on these samples by the Crows Nest Resources Ltd.'s lab, Loring Laboratories Ltd., and David E. Pearson and Associates Ltd. All of the data is included in the above enclosures, but as yet no summary of the data on a seam-by-seam basis is available. The following comments are preliminary in nature to give some idea of the basic quality:

- Based on CSR drill hole data
  - raw ash varies from 15% - 35%
  - volatiles (at 1.6 S.G.) are in the 21 - 22% range
  - sulphur (at 1.6 s.g.) is low (0.3 - 0.5%)
  - RoMax (at 1.6 S.G.) ranges from 1.21 - 1.29
  - Calorific values range from 7400 - 7800 Kcal/kg

- There is evidence of "layering" within seams of "Met." and "Thermal" coal (based on raw FSI values), and therefore some of these seams may have potential for selective mining to optimize the reserves.

ENCLOSURE 13: TEST PIT QUALITY DATA

The M.S.A.N. test pit was intended to be an attempt to obtain bulk samples of individual seams that would be large enough to run through either the thermal or the metallurgical plant to obtain some idea of their individual cleaning characteristics. It was hoped that this data would then be used to determine how these coals could be blended with other Line Creek seams and still match the sales contract quality specifications.

Samples were collected from the following seams:

8U, 8L1, 9U, 9L and 10B.

Unfortunately, due to inadequate coordination at the Plant, the 8U and 8L1 sample was mixed with other coals and not processed by itself. Therefore there is no data available for these seams.

Samples were processed for seams 9U, 9L and 10B with data being obtained for 9U through the metallurgical plant, 9L through the metallurgical and thermal plants and 10B through the thermal plant.

All available data is attached:

9U SEAM - Bulk sample processed through Line Creek Metallurgical Plant
