### 1.1 GENERAL

This report presents the geological work undertaken to date on the Telkwa coal licences in west-central British Columbia held by Manalta Coal Limited. Cumulative work completed during the 1993 and 1994 exploration programs is particularly emphasized, detailing the geology, coal reserves and coal quality of affected license areas. Since acquiring the Telkwa Property in May of 1992 Manalta Coal Limited has undertaken three exploration programs on the Property in as many years.

### 1.2 LOCATION AND ACCESS

The Telkwa Coal Property is located in west-central British Columbia approximately 15 kilometres south of the city of Smithers and about 2 kilometres southwest of the community of Telkwa (Enclosure 1), both of which are situated along the Yellowhead Highway (Highway #16) 11 kilometres apart. Smithers, in turn, is located 380 kilometres by rail east of Prince Rupert and the Ridley Island coal handling facilities (Figure 1.1). Smithers is serviced by commercial aircraft on a daily basis.

The Telkwa Property currently consists of 14,658 hectares held under 58 coal license blocks, measuring approximately 20 kilometres in the north-south direction by 14 kilometres east-west. The Telkwa River flows eastward through the property bisecting it into two approximate halves, both of which contain coal measures of economic significance.

Access to the north side of the property is via Smithers along an all-weather public road which approximately parallels the Bulkley and Telkwa Rivers. The south side of the property is accessed from the community of Telkwa, again by an all-weather

- 1 -

road. Logging roads are common, especially on the southern half of the property, branching periodically from the all-weather access road, allowing access to more remote locations of the property via four-wheel drive and all-terrain vehicles.

The area is serviced by a 500 KV powerline which bisects the property in an approximate east-west direction, running along the south side of the Telkwa River. In addition, Pacific Northern operates an underground natural gas transmission line which also transects the property, parallelling the south side of the Telkwa River and branching northward towards Smithers along the eastern licence blocks.

# FIGURE 1.1

# TELKWA PROPERTY LOCATION MAP

The physiographic setting for the Telkwa property is typically foothills, intermediate to the Bulkley Range of the Hazelton Mountains and the low-lying gently rolling relief of the Nechako Plateau. The Bulkley Range is obvious to the north and west of the property where the landscape is bedrock controlled, while within the property limits and easterly topography is generally rounded and covered with widespread glacial drift. Bedrock on the property is usually obscured as glacial sediments form a shallow mantle over much of the area, exceptions occurring sporadically or along sections of deeply eroded river and stream valleys such as Goathorn Creek.

The principal drainage system on the property is the Telkwa River which flows east across the property until it ultimately drains into the Bulkley River at the community of Telkwa. Major tributaries to the Telkwa River include Pine Creek which drains much of the area on the northern licences, and Tenas and Goathorn Creeks which drain the south.

Elevations within the property limits range from a low of 530 meters above sea level at the Telkwa River's eastern contact with the property boundary to a high of 1375 metres at the property's southernmost extremity near Cabinet Creek. Most elevations, however, lie within 600 and 900 metres.

Vegetation at lower elevations along watercourses consist mainly of cottonwoods, spruce and shrubs. The tree layer is typically composed of large, widely spaced cottonwoods with scattered hybrid spruce and trembling aspen. The understorey is composed of a rich diversity of shrub species which include high-bush cranberry, red-osier dogwood, alder, prickly rose, snowberry and black twinberry. At higher elevations the predominant vegetational cover consists of lodgepole pine, balsam fir and spruce. Understorey species include alder, willow, black twinberry and prickly rose (TAESCO, 1985). Some of the area has been commercially logged and a number of areas have been cleared for agricultural purposes.

Pacific Inland Resources Ltd. of Smithers harvests timber within the license area for the production of commercial building products. One of the principal mills in the area is situated at the outskirts of Smithers along the access road to the north side of the property.

Soils in the vicinity vary in thickness and have developed on glacial till, outwash sediments and occasionally on weathered parent material. Parent material generally tends to be represented by either sedimentary sandstones and siltstones of the Skeena Group or volcanic sediments of the Hazelton Group.

### 1.4 TENURE

The Telkwa Property currently consists of 14,658 hectares (36,221 acres) of coal licences as well as 1295 hectares (3200 acres) of Freehold land collectively held by Manalta Coal Limited (Enclosure 2). Surface ownership rights are held in part by the Crown (approximately 70% of the property surface area), in part by Manalta Coal Ltd. (approximately 8% in the form of Freehold land) and in part by third party land owners. The property coal licences are summarized on Table 1.1.

# TABLE 1.1: TELKWA PROPERTY - COAL LICENCE SUMMARY

### 1.5 HISTORICAL PERSPECTIVE

Coal was initially discovered in the Telkwa area at about 1900 although production did not commence in the Goathorn Creek area until 1918. On the north bank of the Telkwa River the Aveling (Telkole) Mine produced coal from 1921 to 1922 and again from 1940 to 1945. Telkwa Colliery (McNiel Mine) on the south side of the Telkwa River began producing in 1923 (Malott, 1990). Initial mining production was mainly for local consumption until after 1930 when underground operations were initiated at Bulkley Valley Collieries near Goathorn Creek. Production since that time has been sporadic, however, with underground operations often curtailed by structural complications and inadequate pre-development exploration.

Since 1950 the Telkwa Coalfield has been actively prospected by a variety of companies. The following is a summary of the area's exploration activities since that time. Regional geology, plotted annual exploration drill-holes and identified resource areas are found within Enclosure 3.

- **1951** - The Government of Canada conducted a regional survey, much of which included the Telkwa licence area.

- 1969 - Canex Aerial Limited completed a drilling program of approximately 20 boreholes on the Telkwa North licenses.

- **1977 to 1978 - Cyprus Anvil Mining** completed a rotary drilling program within the Telkwa South licences.

- **1979** - Shell Canada/Crowsnest Resources Ltd. completed 13 rotary drill-holes, 4 of which were located on Telkwa South licenses, and the remaining 9 situated on the north side of the Telkwa River. Chip samples were not recovered for analytical testing.

- 7 -

- 1981 - Shell Canada/Crowsnest Resources Ltd. completed a mapping and exploration drilling program which consisted of 11 rotary holes and one diamond drill-hole, all of which were spaced randomly throughout the Telkwa property. Coal samples were recovered from 4 of the rotary holes as well as the diamond drill-hole for analyses.

- 1982 - Shell Canada/Crowsnest Resources Ltd. drilled 72 boreholes on the property, the majority of which were located on the south side of the Telkwa River. Of the 72 holes, 7 were rotary drill-holes and 65 were diamond drill-holes. Coal samples were collected and analyzed from all holes which intersected significant coal units.

- 1983 - Shell Canada/Crowsnest Resources Ltd. completed 69 diamond drill-holes on the Telkwa South licences, most of which were located within what has been designated as the Pit #3 resource area. Included within the program were a small number of large-diameter coreholes which, along with all other drill-holes that intersected significant coal units, were sampled and had coal analyses performed. Of the 69 boreholes completed, 11 were situated within the proposed Pit #3 test-pit limits, to provide a preview of the pit development.

Based upon drill-hole information a 219 tonne bulk sample from 7 seams was subsequently extracted from a test-pit located within the Pit #3 area. A full suite of coal quality analyses was performed, including testing on various simulated washplant products.

- 1984 - Shell Canada/Crowsnest Resources Ltd. completed 44 diamond drill-holes, the majority of which were located within the Pit #3 resource area on the south side of the Telkwa River. Less than 10% of the holes were drilled on the Telkwa North coal licences. All significant coal units were sampled and analyzed.

- 8 -

- 1985 - Shell Canada/Crowsnest Resources Ltd. completed 4 diamond drill-holes, all of which were located north of the Telkwa River. All significant coals were sampled and analyzed.

- 1986 - Shell Canada/Crowsnest Resources Ltd. completed 4 diamond drill-holes, again located on the Telkwa North coal licences within an area that has been designated as Pits #7 and #8 Resource Area. Coal analyses were performed on all significant seams.

- 1988 - Shell Canada/Crowsnest Resources Ltd. completed an exploration program exclusive to the Telkwa North licences which consisted of initially completing approximately 3.5 kilometres of surface geophysics to highlight potential target locations. The area was subsequently drilled with 14 diamond drill-holes from which coal samples were collected and analyzed.

- 1989 - Shell Canada/Crowsnest Resources Ltd. completed an exploration program consisting of drilling and surface geophysics on the Telkwa North coal licences, and reflection seismic exploration within the Pit #3 area of the Telkwa South licences. In addition a large-diameter coring program was undertaken specifically targeted at obtaining a bulk sample from the Pit #7 resource area.

The conventional exploration drilling program included 31 bore-holes, 18 of which were rotary drill-holes, and the remaining 13 continuous core diamond drill-holes. Coal samples for analyses were collected from all holes which intersected significant coal units although only cored bore-holes were provided a full analyses. Recovered rotary chip samples were not considered representative. North Telkwa surface geophysics included approximately 15.4 kilometres of geophysics shared between the Pit #7 resource area, the Pit #8 proposed waste dump area and the proposed infrastructure facilities location.

- 9 -

Upon completion of the conventional exploration program four previously drilled sites in the Pit #7 area were selected as locations for largediameter (6 inch) core-holes. From these a bulk sample from 7 seams was extracted and provided a full analysis.

As part of a joint investigation managed by the Coal Mining Research Company of Devon, Alberta, 4 seismic lines totalling 4.9 kilometres were laid out and a reflection seismic exploration program completed. The area chosen for the investigation was within the Pit #3 resource area where reasonable drill-hole control had previously been established.

- **1989** - The Geological Survey of Canada, as part of a province-wide study of coal quality, drilled 9 core-holes for a combined total length of 280 metres in the vicinity of the old Bulkley Valley Collieries site near Goathorn Creek. Two of the holes were drilled in the vicinity of the historic Avelling Mine. All coal intersections were sampled and subsequently analyzed.

- **1992** - Manalta Coal Ltd. of Calgary, Alberta acquired the Telkwa Coal licences on May 1st of 1992 from Shell Canada/Crowsnest Resources Ltd.. Later that year Manalta Coal conducted an exploration program which included 3.6 kilometres of surface geophysics, a regional airborne magnetic survey review and 43 drill-holes. The surface geophysics and 39 of the 43 holes drilled were located on the Telkwa North licences, while the remaining 4 drill-holes were completed on the south side of the Telkwa River in the Tenas Creek area.

Of the 43 bore-holes completed 19 were diamond core-holes, 3 were rotary core-holes and 21 were drilled utilizing conventional rotary drilling techniques. All holes completed in the Tenas Creek area were of the rotary variety although one was rotary cored through its coal measures. All significant coal seam intersections from cored drill-holes were sampled and analyzed.

Coincidental with the exploration drilling program representatives from the British Columbia Ministry of Energy, Mines and Petroleum Resources (MEMPR), and the Institute of Sedimentary and Petroleum Geology (ISPG) were on site to conduct coalbed methane desorption tests on selected Telkwa coal samples. The study conducted by the MEMPR and the ISPG was part of a regional study of methane desorption in British Columbia coalfields.

- 1993 - Manalta Coal Ltd. completed an exploration program consisting of 53 drill-holes shared between the Telkwa North and Telkwa South coal licences. In addition a geotechnical and surficial geology program was completed by Piteau Engineering on behalf of Manalta Coal Ltd. which included rock strength testing on selected cores, approximately 19 kilometres of surface geophysics and 10 till sample sites. All surficial geology studies were completed within a proposed tailings pond investigation area located near the Pit #7 and #8 Resource areas.

The Tenas Creek exploration area on the south side of the Telkwa River was the focus of 26 drill-holes, targeted at obtaining additional coal quality information and further delineation of the field's limits. Also within the Telkwa South coal licences, 5 drill-holes, all of which were cored, were completed within the Pit #3 Resource Area to obtain additional coal quality information.

Exploration completed on the Telkwa North coal licences consisted of 2 drill-holes within the limits of the Pit #8 Resource Area, 11 drill-holes dedicated to further exploration of the Pit #8 coal trend beyond the pit limits, and 9 reconnaissance drill-holes completed proximal to the Pits #7 and #8 Resource areas.

Of the 53 bore-holes completed in 1993 11 were diamond-drilled coreholes, 10 were rotary core-holes (including one 1992 drill-hole which was

- 11 -

cored in 1993) and 33 were drilled utilizing conventional rotary techniques. All significant coal seam intersections from cored drill-holes were sampled and subsequently analyzed.

- 1994 - Manalta Coal Ltd. completed their third annual exploration program, consisting of geological surface mapping and the completion of 56 rotary drill-holes, 8 of which were cored at least partially. Work was undertaken on both sides of the Telkwa River, although dominated slightly by drilling activities on the southern coal licences where 32 drill-holes were completed.

Of the 32 drill-holes completed on the Telkwa South coal licences 13 were dedicated to further exploration of the Tenas Creek resource area, while 19 exploratory drill-holes were completed to evaluate the coal-bearing potential of the Tenas Creek West coal licences. Drilling on the Telkwa North licences included 14 exploratory drill-holes within the MCL (Whalen) Freehold Block, 8 within tentative wastedump areas between Pit #8 and Whalen Block, and 3 drill-holes completed proximal to the Pit #7 resource area. All cored coal seam intersections were sampled and subsequently analysed.

### 1.6 ACKNOWLEDGEMENTS

The work undertaken for the Telkwa geological study was carried out by various contractors and consultants under the management and supervision of Manalta Coal Limited's staff. This report was prepared by Mr. A. Ledda of Manalta Coal Ltd. with input from the following groups:

- Chemex Labs Ltd. for geochemical analyses.
- Drs. Barry Ryan and Alex Matheson of the British Columbia MEMPR.
- Loring Laboratories Ltd. for coal quality analyses.

- Norecol, Dames and Moore for geochemistry technical support.
- Piteau Engineering Ltd. for tailings pond geotechnical studies.

Mr. Angelo Ledda of Manalta Coal Ltd. has received a Bachelor of Science Degree in Geology (1986) from the University of Calgary as well as a Diploma in Petroleum Technology; Geology (1982) from the Southern Alberta Institute of Technology (S.A.I.T.). Since graduation with his B.Sc. he has been employed as an exploration and development geologist with Gulf Canada Resources Ltd., taught evening classes in the Petroleum Technology; Geology program at S.A.I.T., and is currently an Senior Project Geologist with Manalta Coal Ltd.

Mr. Angelo Ledda is a Professional Geologist, registered with the Association of Professional Engineers, Geologists and Geophysicists of Alberta (APEGGA). His 9 years of work experience as a geologist includes some work within the oil and gas industry although the majority of his experience has been within the coal industry on deposits situated throughout western Canada. Much of his coal experience lies within studies conducted in the Bowser Basin, including the Klappan, Groundhog and Telkwa Coalfields.

2.0 GEOLOGICAL WORK

On the basis of geological work carried out in previous years by Manalta Coal Ltd. and various other groups, the 1993/94 exploration programs conducted by Manalta were designed to further delineate high potential mining targets and to initiate reconnaissance exploration of other areas. They were also intended to provide additional data on the geology, reserves and coal quality of those potential mining targets. Licence blocks affected by the 1993 and 1994 exploration programs are illustrated on Figure 2.1.

### 2.1 SCOPE OF WORK

Work completed during the 1993 field exploration program included 53 exploration drill-holes, the investigation of a potential tailings pond site, and reclamation. The entire exploration program spanned two months from late August to late October, 1993. The tailings pond investigation consisted of 10 shallow test-holes and approximately 19 kilometres of surface geophysics. Surface geophysics work took place coincidentally with drilling activities while reclamation continued until adverse weather halted reclamation efforts.

Work undertaken during the 1994 exploration program included geological surface mapping, the completion of 56 exploration drill-holes, and reclamation. Geological mapping progressed throughout the latter half of July while drilling activities spanned from mid-August to mid-October, 1994. Reclamation efforts took place coincidentally with drilling activities and continued, virtually uninterrupted, to early November.

### 2.1.1 Surface Geophysics

Surface geophysics were utilized by Piteau Engineering Ltd. on behalf of Manalta Coal as a tool to investigate the surficial geology as it pertains to

- 14 -

suitability for a tailings pond location. Specifically the objectives of the study were to describe unconsolidated overburden characteristics and thickness, bedrock characteristics, and depth to groundwater. Affected licence blocks included CL4276, CL4277, CL8210 and CL8211, where 21 kilometres of brush-line were cut and surface geophysics completed. Specific methods of geophysical investigation included electrical conductivity, magnetometer, very low frequency electromagnetics, direct current resistivity and seismic refraction. Details and results of the tailings pond investigation are presented within the report prepared by Piteau Engineering Ltd., specifics of which are included as Enclosure 5. Locations of the geophysical lines are included within the Telkwa North/South Geology maps, Enclosure 4.

### 2.1.2 Drilling

The exploration component of the 1993 field season consisted of 11 continuous core diamond drill-holes, 10 rotary core-holes (including one core from a 1992 bore-hole) and 33 conventional rotary drill-holes, for a total of 5,769 metres drilled. During 1994 56 drill-holes were completed, of which 48 were drilled utilizing conventional rotary techniques and 8 rotary cored, for a cumulative 1994 total of 5,826 metres.

All drill-holes, summarized for 1993 on Table 2.1, and for 1994 on Table 2.2, were geophysically logged upon completion and surveyed prior to site reclamation. Piezometers were installed at three 1993 drill-hole locations in order to monitor groundwater movement within specific stratigraphic horizons. No piezometers were installed during 1994. To date, including 1993/94 drilling, 416 drill-holes have been completed on the Telkwa Property since 1979 (Enclosure 6).

Wireline as well as conventional coring techniques were employed during

- 15 -

the exploration programs. Diamond drill-holes were continuously cored, extracting 7.62 centimetre diameter (HQ) core from the top of competent strata through the entire length of the hole. On occasion, like diamond drilled core-holes, rotary wireline core-holes were also continuously cored throughout their entirety. Normally, however, a conventional rotary pilot hole was drilled initially at the site location and subsequently a second adjacent hole was drilled, where selected coal units were cored. Normally rock units between core intervals were conventionally drilled. At rotary core locations 10.0 centimetre diameter core was recovered. Core recoveries from both coring methods were excellent, generally ranging from 80% to 100%.

As part of the surficial geology investigation of the potential tailing pond location 10 drill sites were selected and drilled, and the surficial geology described. At these locations a diamond drill with a tri-cone bit was used to drill to bedrock or to a maximum depth of 8.2 metres.

For both the 1993 and 1994 exploration programs a Failing 1250 and an Ingersol Rand TH60 truck-mounted drilling rig were used to complete the rotary component of the program while an Acker Diamond Drilling Rig completed all diamond drill-holes. McAuley Drilling Co. of Spruce Grove, Alberta and Cora Lynn Drilling of Strathmore, Alberta completed the rotary component of the program while J.T. Thomas Diamond Drilling of Smithers, British Columbia completed all diamond drilling.

l

#### TELKWA 1994 DRILL - HOLE SUMMARY LE 2.1

### 2.1.2.1 Drill-hole Numbering

Drill-holes completed on the Telkwa Property between 1979 and 1989 were not numbered utilizing a common numbering scheme. As a result, in 1992, all drill-holes completed on the property were renamed to reflect a common system. The original numerical component of the name was retained to avoid confusion but prefixes denoting the year drilled and the type of drill-hole were made consistent. An example of the adopted system would be T85D-502 where:

- .T denotes it as a Telkwa Property drill-hole; TG as a
  - Telkwa Surficial Geology test-hole.
- 85 classifies it as being drilled in 1985.
- D denotes it as a diamond drill-hole; R as a rotary.502 is its original numerical component.

For rotary core-holes a C would follow the numerical component. A complete drill-hole listing is provided within Enclosure 6.

### 2.1.2.2 Geophysical Logging

When physically possible all exploration drill-holes completed within sedimentary rock were open-hole geophysically logged shortly after drilling was suspended. Where poor downhole conditions were encountered a slimline gamma-density tool was lowered through the drillstem so as to obtain at least one complete geophysical log of the hole. Detail logging (1:20 Scale) was undertaken over significant coal seam intervals only. Surficial geology test-holes were not geophysically logged due to their shallow completion depths nor were some 1994 bore-holes completed within volcanic bedrock, particularly those containing excessive thicknesses of poorly consolidated Tertiary overburden sediments.

Copies of geophysical logs for each borehole are presented within Enclosure 27. In most cases downhole conditions were satisfactory and the following open-hole geophysical log responses were obtained:

Gamma Ray Generai	1:100 Scale
Long Spaced Density General	1:100 Scale
Dipmeter General	1:100 (on selected holes)
Caliper	
Deviation	
Gamma Ray Detail	1:20 Scale
Long Spaced Density Detail	1:20 Scale
Bed Resolution Density Detail	1:20 Scale

### 2.1.2.3 Drill-hole Logging, Sampling and Analysis

All core-holes completed during the 1993 and 1994 exploration programs were logged in detail (Enclosure 7) by geologists on site. In 1993 a total of 364 coal ply samples were collected while in 1994 there were 149 samples recovered. During both seasons rock samples from representative core-holes were also collected for subsequent analyses to determine potential acid rock drainage (ARD) characteristics. Cuttings descriptions from all rotary drillholes, as described in the field, are found within Enclosure 8. Specific details of analyses conducted and test results are discussed in Section 4.0.

- 20 -

### 2.1.3 Geological Surface Mapping

Geological surface mapping completed during the 1994 exploration program was concentrated mainly on the Telkwa South coal licences within the incised drainage systems of Cabinet and Webster Creeks, and on areas of high topographic relief where outcrop exposures were unobscured. Coal licences where mapping was undertaken include CL4260, CL4261, CL4262, CL4264, CL4282 and CL8426.

### 2.1.4 Reclamation

Reclamation activities were undertaken in areas disturbed by recent exploration activities, as well as those areas disturbed by previous years' activities which were considered to require additional work. All disturbed areas were recontoured, reseeded and fertilized using Forestry approved mixtures. Access trails on sloping ground were water barred for erosion control, and additional topsoil was added to areas that inhibited new plant growth. All work was carried out in accordance with the regulations and guidelines of B.C. Forestry. Areas which were not reclaimed in the disturbance year due to the onset of adverse weather were completed the following spring.

### 3.1 REGIONAL GEOLOGIC SETTING

During Jurassic and Cretaceous time much of the western portion of British Columbia was formed as the result of several terranes that moved slowly toward and eventually collided with the North American craton. The Telkwa coalfield is the product of sedimentation that occurred as one such terrane, the Stikine Terrane, pushed eastward to eventually become sutured to the North American landmass (Richards, 1988).

Successor basins, which formed in response to the approaching terrane, were the focus of rapid sedimentation, subsidence and increased tectonic activity. One such successor basin, the Bowser Basin, had developed during Middle Jurassic time near the present-day location of Smithers. It was a centre of deposition, bounded on the north by the Stikine Arch, on the south by the Skeena Arch and on the east by the early uplifting of the Columbian Orogeny. The Telkwa coalfield developed along the northern flank of the Skeena Arch near the southern limit of sedimentary rocks in the Bowser Basin (Figure 3.1) (Palsgrove and Bustin, 1991).

Deposition of the coal-bearing sediments in the Telkwa area was initiated into the Bowser Basin during the Lower Cretaceous, following uplift and erosion of the Skeena Arch. Although this sedimentation initially came from the south and west, an eastern provenance soon dominated, a response to the increased uplift of the Columbian Orogeny. The result in the Telkwa area is represented by more than 500 metres of coal-bearing strata referred to as the Lower Cretaceous Skeena Group. In the Telkwa coalfield Skeena Group sediments unconformably overlie Jurassic Hazelton volcanics.

- 22 -

Figure 3.1. Tectonic Elements of British Columbia (R.J. Palsgrove, 1990).

- 23 -

### 3.2 STRATIGRAPHY

Sedimentation of Skeena Group sediments occurred throughout the Lower Cretaceous, during which time deposition was influenced by two regressive / transgressive episodes. As a result the stratigraphic sequence (Enclosure 9) is divisible into four lithostratigraphic units (Palsgrove and Bustin, 1989) described below. Porphyritic Tertiary and Cretaceous intrusive dykes and sills commonly disrupt local stratigraphy as does a large Tertiary granodiorite plug identified on the northern coal licences.

### 3.2.1 Unit I

The basal unit, Unit I, was deposited in a fluvial environment on an eroded Hazelton volcanic basement of Jurassic age. In the Telkwa area Unit I may be in excess of 100 metres in thickness and consists mainly of conglomerate, sandstone, mudstone and coal. Sands and gravels were typically deposited in braided channels and bars while mudstones accumulated in floodplains. Coals within this unit, collectively referred to as Coal Zone 1, formed in poorly drained backswamps and are characterized by lateral variation throughout the study area. Deposition of Unit I ended with a marine transgression and deposition of Unit II.

### 3.2.2 Unit II

Unit II was deposited within a deltaic / shallow marine environment and consists of up to 140 metres of sandstone, silty mudstone and occasional thin coaly mudstone. Sands were deposited in distributary channels and mouth-bars while mudstones and silty mudstones accumulated in interdistributary bays. Thin discontinuous peat beds, none of which are of economic significance, accumulated in local salt marshes.

### 3.2.3 Unit III

Unit III is indicative of the second regressive episode for the area and represents the deposition of the main coal-bearing stratigraphic sequence. The unit averages 85 metres in thickness and comprises of sandstone, siltstone, carbonaceous mudstone and thick, laterally extensive coal seams. Restricted nearshore marine, tidal flat and coastal swamp environments persisted throughout much of the deposition of Unit III. Sandstone units were deposited within tidal channels while interbedded sandstones and siltstones were deposited nearshore within intertidal environments. Mudstones are representative of tidal flat deposits. Indications are that there was significant marine influence during deposition of the entire unit.

Coal Zones 2 through 11 are represented in Unit III, collectively consisting of up to 17 coal seams of economic significance. The coal zones were likely formed in freshwater peat swamps, located landward of the tidal flat, somewhat isolated from influxes of brackish water. The presence of sulphur in some of the coal seams suggests, however, that the peat was infiltrated periodically by marine water. Thus, the major coal seams are interpreted to have formed from peat accumulated in a freshwater marsh that was proximal to a brackish environment. The Snuggedy Swamp of South Carolina is considered a modern analog for the paleoenvironment in which Unit III was deposited.

### 3.2.4 Unit IV

Unit IV overlies the coal measures and represents a marine transgression that terminated coal deposition over the study area. The unit exceeds 150 metres in thickness and consists of sandstone overlain by silty mudstone. The basal sandstone is a transgressive lag deposit while the remainder represents deposition within a near-shore, shallow marine environment.

- 25 -

Since deposition of the Skeena Group of sediments during the Lower Cretaceous the Telkwa area has undergone at least two episodes of structural significance. The Upper Cretaceous of the Bowser Basin reflects a time of deformation, when high angle faulting and plutonism were occurring eastward within the Omineca Crystalline Belt, and increasing uplift was occurring to the west. This was a result of the suturing of the Stikine Terrane to the North American craton and also the effects of additional terranes approaching from the west. Although folding in the Telkwa area was not as significant as in other portions of the basin, high angle faulting roughly trending in a north-south direction are apparent in the Telkwa coalifield, especially on the south side of the Telkwa River. Porphyritic Late Cretaceous dykes and sills also occur locally within the coal measures.

During the Tertiary much of the area on the north side of the Telkwa River was intruded by a large granodiorite and quartz monzonite intrusion. The igneous body, which vertically intruded the Skeena sediments, complicated the structural geology of the area further. This is especially apparent at close proximities to the intrusive body on the northern coal licences. Structural repercussions in the Skeena sediments appear to be represented by high angle faulting, establishing a mosaic of structural blocks that have been rotated and tilted into a variety of orientations. No specific orientation has been observed to the faulting although faults are apparent in concentric geometries near the intrusive body and also appear to crudely radiate from the intrusive edge. Fault displacements have been observed to range from only a few metres to more than 150 metres.

Although bedding orientations within the Telkwa Property resource areas tend to be fault block controlled, each with independent orientations, dips normally range from 10 to 30 degrees. In the fault blocks associated with the Pit #3 resource area dips are typically 20 degrees to the east, while within the blocks of Pit #7 & #8 they average 17 degrees to the east and northeast respectively. In the Northwest Area, block orientations are to the southeast and southwest, with dips ranging from

- 26 -

10 to 35 degrees. Tenas Creek orientations are consistently easterly dipping, normally ranging from 9 to 22 degrees. Within the MCL Whalen Block orientations vary but typically range from 15 to 25 degrees to the east/southeast.

### 3.4 DETAILED GEOLOGY

Exploration work completed by Manalta Coal Limited in 1993 and 1994 was distributed somewhat evenly between the North and South Telkwa coal licences. On the north side of the Telkwa River exploration drill-holes were completed within the Pit #7 & #8 resource areas, the MCL Whalen Freehold Block, and the tailings pond investigation site. These drill-holes were dedicated mainly to the further delineation of the Pit #8 coal trend and reconnaissance drilling adjacent to existing resource areas. Work completed in 1993 also included a tailings pond geophysical survey over the tailings pond study area and a shallow surficial geology drill-hole program.

On the south side of the Telkwa River the bulk of drilling occurred within the Tenas Creek resource area to further delineate field limits, and within the West Tenas Creek area where reconnaissance exploration drilling was initiated. Five additional drill-holes, completed in 1993, were drilled within the Pit #3 resource area, also on the south side of the Telkwa River.

The economic coals found represented within the Pits #3, #7, #8, and Northwest resource areas are those of lithostratigraphic Unit III (Seams #2 - 11). In the Tenas Creek, Cabinet Creek and MCL Whalen areas, however, the main seams of interest are those of the Seam #1 coal sequence of Unit I.

The Pit #7 and #8 resource areas have been modelled utilizing the Lynx Mine Modelling System. The resultant models are considered to be an accurate representation of the geological information obtained to date. The 1993/94 exploration programs have resulted in updates to the geological models, most-

- 27 -

notably to the southeast end of the Pit #8, where the coal trend has been extended. Additional updates include seam nomenclature of some seams found within Pit #7.

No additional work since 1992 has occurred on the coal licences within the Northwest Area. The area has not been computer modelled to date, as additional drilling is considered necessary to accurately determine its geometry. Minimal work was undertaken within the Pit #3 area in 1993, and time restraints have not yet allowed modelling of the deposit within the Lynx system. The Tenas Creek deposit has also not been computer modelled via the Lynx System as additional exploration is anticipated.

The stratigraphic columns prepared for each of the main resource areas (Enclosure 9) clearly illustrate the typical stratigraphy found within each of the resource areas. It also shows some of the regional variations and trends which occur within seam and interseam lithologies throughout the Telkwa Coalfield. Some of the more notable trends are as follows:

- The coal seams within Lithostratigraphic Unit I, collectively referred to as Seam #1, are separated from the overlying coals of Unit III by up to 140 metres of shallow marine origin sediments. As such the seams have not been intersected by drilling, except on occasion, within most of the resource areas drilled to date. The exception is within the Tenas Creek Resource Area, drilled extensively in 1993 and 1994, where the Unit I coals are the represented target of interest. Correlation of the #1 seams between resource areas is currently unrefined, however, as additional information is required to further determine the consistency and lateral variability of individual seams. Intersections of the #1 seams within the MCL Whalen Block indicate that the seam, at least in this area, is subject to considerable variability, a result of erosional forces by fluvial systems.

- Seam #2 remains consistent throughout much of the property although

**-** 28<sup>.</sup>-

thin partings are apparent within the Pit #3 and #7 resource areas. The seam does, however, exhibit some thickness variability over short distances especially within the northwest portion of Pit #8. Seam #2 Upper, which overlies Seam #2, is thin and developed only within the eastern resource areas north of the Telkwa River. Seam #2 Lower, which underlies Seam #2, also occurs on the northern side of the river but remains significant only within the western resource areas.

- Seam #3 remains one of the most consistent seams in the stratigraphic sequence of Unit III. It is found throughout the resource areas which exploit Unit III, and is consistently split into Seams #3 Lower and Upper by a mudstone parting rarely exceeding one metre in thickness.

- Seam #4 is normally well-developed throughout each of the resource areas but is locally absent from a small area in the southeast portion of Pit #8. Seam #4 Upper, which overlies the #4 Seam, is absent from Pit #7 and the eastern half of Pit #8, but occurs throughout the western part of Pit #8, the Northwest Area, and Pit #3. The parting thickness between Seam #4 and #4 Upper increases progressively in a northwesterly direction attaining a maximum thickness of more than 7.0 metres in the Northwest Area.

- Seam #5, a very well-developed seam, is found throughout the property. It splits, however, midway through Pit #8 where it is represented in Northwest area and the west half of Pit #8 as Seams #5 Lower and #5 Upper.

- Seam #5ex is undeveloped throughout most of the property but progressively develops within the Pit #8 resource area, becoming increasingly apparent on the west side of Pit #8. Within the Northwest Area the seam continues to thicken and represents one of the thickest and best developed seams of the area.
- Seam #6 exhibits considerable variability between the resource areas, splitting from a single seam in Pit #3 to as many as 3 seams in Pit #7. Throughout Pit #7, Pit #8 and Northwest Area the seam is represented as #6 Lower and #6 Upper, separated by a parting normally averaging approximately one metre in thickness. In the Pit #7 area Seam #6 Lower is further split by another parting normally not exceeding 0.50 metres in thickness.

- Although generally thin and considered uneconomic throughout most of the resource areas Seam #7 is laterally continuous and shows little variability throughout the coalfield. The exception is within Pit #7 where the seam is absent from the sequence.

- Seam #8, although present throughout most of the resource areas, exhibits considerable variability with respect to seam thickness, often over short lateral distances. Seam #8, and those seams which overly it, are not well represented within the Pit #7 area since most of the upper portion of the Unit III sequence was eroded from that area prior to glaciation.

- Seam #9, due to its variable thickness and poor quality characteristics, is rarely considered of economic significance. The seam is characterized by visible pyrite banding and as a result has higher than average raw sulphur values in comparison to other seams. Like underlying Seam #8 it often exhibits seam thickness variability and lateral discontinuity.

- Seam #10 is a relatively consistent seam, present throughout most of the Pit #3, Pit #8 and Northwest areas. The seam varies in thickness, however, often over short lateral distances. - Seam #11, the roof of which forms the top of Lithostratigraphic Unit III, is found throughout the Telkwa North resource areas where it is usually a consistent, continuous seam. It does, however, exhibit some regional thinning within the northeast segment of Pit #8.

- Four notable sandstone units have been identified within or proximal to the Seam #2 to #11 coal seam package. The #2 Sandstone, which underlies the #2 and #2 Lower seams represents the thickest, most consistent and predictable sandstone unit of the four. Forming the top of Lithestratigraphic Unit II, it is a massive sandstone in excess of 10 metres in thickness which has been observed to commonly contain pelecypod shells or shell fragment horizons within it. The sandstone unit is most strongly developed on the north side of the Telkwa River.

The #3 Sandstone, stratigraphically located in Unit III between Seams #3 Upper and #4, is present throughout all of the resource areas but remains thickest and best developed within the Pit #3 area south of the Telkwa River. The sandstone unit thins considerably in Pit #7 and continues to thin, becoming finer-grained westward into Pit #8 and Northwest Area.

The #7 Sandstone is situated stratigraphically within Unit III between Seam #7 and #8 and is laterally continuous throughout the resource areas on both sides of the Telkwa River, although is most strongly developed in the Pit #3 area. The unit commonly is interbedded with finer-grained lithologies, most apparent on the north side of the Telkwa River.

The #11 Sandstone, or Unit IV Sandstone as it is sometimes referred to, represents the base of Lithostratigraphic Unit IV and usually directly overlies Seam #11. This marine sandstone is regionally correlatable across the resource areas, displaying only minor variability. The unit does, however, tend to be slightly thinner in Pit #3 than within Pit #8 and Northwest Area.

- 31 -

#### 3.4.1 Pit #3 Resource Area

Between 1979 and 1984 the Pit #3 resource area had been extensively explored resulting in considerable volumes of information accumulated on the area's Unit III coal measure stratigraphy. The seams (#2 - #11 seam package) subcrop along the western edge of the area, roughly paralleling the Goathorn Creek valley. Most of the seams deteriorate easterly, becoming thinner and poorly developed suggesting that locally, during deposition, a restricted nearshore marine environment persisted to the east (Palsgrove, 1990).

The Pit #3 area is characterized by an east-dipping stratigraphy, repeatedly broken by a series of north/south trending normal faults. Regional dips range from 10 to 35 degrees, averaging 20 degrees, while normal fault displacements range up to 20 metres. In 1993, 5 core-holes were completed at selected sites and additional coal quality information from several seams was collected.

### 3.4.2 Pit #7 Resource Area

In 1993/94 there were few additional drill-holes completed within the limits of the Pit #7 resource area, although several drill-holes were completed proximal to the area. Some of these drill-holes, particularly those occurring stratigraphically down-dip of the Unit III coal measures, intersected the #1 Seam coals of Unit I. In addition, drilling completed within the southeast extension of Pit #8, adjacent to Pit #7, has provided additional stratigraphic information relating to seam relationships between the two resource areas, allowing modifications to correlations to some seams of Pit #7. Significant changes are summarized within Table 3.1.

## Table 3.1

- 33 -

To date 19 drill-holes have intersected the Unit III coal measures (Seams #2 - 11) within the Pit #7 area (Enclosure 10). Drill-hole spacing for the area is currently approximately 125 metres. Enclosure 11 presents a summary of all seam intersections and average seam thicknesses encountered within the Pit #7 resource area to date. Individual drill-hole details and seam intersection data is provided within Enclosure 12.

The coal measures trend in a north-south direction and dip east to northeastward until they terminate against a northeast-southwest trending near vertical fault. This normal fault exhibits considerable displacement (approximately 150 metres) juxtaposing thin coal seams possibly of the #1 seams against the Unit III coal seams found in Pit #7. The coal measures also abruptly terminate to the north where Skeena sediments have been intruded by a large Tertiary granodiorite plug. The intrusive truncates the sediments at nearly 90 degrees to bedding and extends beyond Pit #7, further disrupting the coal measures of Pit #8 and Northwest Area. Small-scale faulting has been identified at close proximities to the intrusive contact in other areas and is suspected in Pit #7 as well. The coal seams subcrop to the west and south, as illustrated on cross-sections 7A through 7E (Enclosure 13). Cross-section locations are referenced on the Pit #7 Geology Map (Enclosure 10).

#### 3.4.3 Pit #8 Resource Area

Current exploration for the Pit #8 resource area is such that 55 drill-holes intersect the coal measures of the #2 - #11 seam package of Unit III, providing a drill-hole spacing of approximately 150 metres or less. Drill-hole data has identified that the area consists of two main parallel trending fault blocks which present a repetition of the Unit III coal-bearing sequence (Enclosure 14). Displacement on the normal fault separating the two

- 34 -

blocks ranges from 40 metres near its southeastern end, to 80 metres at its northwestern terminus with the Tertiary intrusive body. Additional normal faulting has been identified by 1993 drilling within the southeast portion of Pit #8. These faults, trending approximately perpendicular to the regional strike of the area, have displacements ranging from 20 to 80 metres. They are known to break and juxtapose the #2 to #11 coal seam package into a series of smaller fault blocks. Several smaller-scale displacement faults have also been identified, normally occurring at close proximities to the intrusive body.

The coal seams subcrop to the southwest and are constrained on the northeast by the granodiorite intrusive. An area of intense faulting and the absence of coal-bearing sediments terminates the Pit #8 resource area to the northwest. Although displaced by normal faulting the coal trend continues to the southeast, and may continue as far south as the Telkwa River, where the trend is presumed fault terminated. Indications are that the coals historically exploited by the Aveling Mine are extensions of the same seam package, suggesting that additional normal faulting may occur beyond the current limits of drill-hole control. Additional exploration is required to further determine the trend geometry in proximity to the Telkwa River.

Bedding orientations throughout the resource area are generally to the northeast as indicated by area cross-sections 8A through 8L (Enclosure 17). Cross-section locations are referenced on the Pit #8 Geology Map (Enclosure 14). Seam intersection data has been summarized within Enclosure 15 while specific drill-hole details and coal quality information are found within Enclosure 16.

- 35 -

#### 3.4.4 Whalen Block Resource Area

Within the Whalen Block exploration activities in 1994 included 14 drillholes. Drilling in 1994 has indicated the presence of coals, represented from both stratigraphic coal zones, Unit I and Unit III. Exploration also indicated the localized presence of structurally complex areas where additional exploration is required to fully evaluate seam geometries. The geology map for the area, Enclosure 18, illustrates the approximate subcrop position of the #1 Seam based upon findings to date. However, small-scale faulting is suspected throughout the area. Specific drill-hole details for the Whalen Block are provided within Enclosure 19.

#### 3.4.5 Tenas Creek Resource Area

The coal measures of Tenas Creek Resource area (Enclosure 20) are representative of the #1 Coal Zone of Unit I and may be correlatable, although fault displaced, to seams in the vicinity of Cabinet Creek. To date a drill-hole spacing of 500 metres has been established at Tenas Creek and 24 drill-holes have intersected the seam sequence. Exploration in 1993/94 has established field limits for the deposit and has established an understanding of the Unit I stratigraphy and seam quality. A summary of drill-holes and seam intersection data in the Tenas Creek area, including those of Cabinet Creek, is provided within Enclosure 21. Specific drill-hole details and coal quality are presented within Enclosure 22.

The Tenas Creek stratigraphy trends at approximately 145 degrees and dips gently east / northeastward throughout most of the field. However, along the eastern side of the resource area the coals lie within a synform where they are likely broken, dipping steeply southwestward. The coals within the east limb of the synform either subcrop or are terminated at depth against a north / south trending fault which juxtaposes the Unit I coal

measures against volcanics, presumably of the Hazelton Group. Bedding orientations on the west limb range from 9 to 22 degrees, gradually increasing towards the southern limits of control in the resource area. Orientations along the east limb range up to 45 degrees although additional work is required to further define this structure.

Other than occasional erosional channel features which have eroded segments of the coal measures within their areas of influence, the #1 seams are laterally continuous throughout the extent of the field. Further exploration is required to fully determine the erosional impact of these Cretaceous paleochannels. Thin, discontinuous coals have sometimes been found developed within the confines of these channel structures.

At the field's northern limits Tertiary sediments, presumably associated with the glacial paleochannel of the Tenas Creek drainage, abruptly disrupt the local coal measures stratigraphy. Within the confines of the paleochannel a thickly interbedded sand and gravel blanket in excess of 85 metres was deposited, which now overlies the deeply eroded Skeena Group stratigraphy. The field's southern limits are not well understood and additional exploration is required to adequately determine the area's geometry as well as its relationship with the underlying Hazelton Volcanic basement. Tenas Creek coal-bearing sediments lie unconformably over Jurassic Hazelton volcanic rocks.

The typical stratigraphic column for the Tenas Creek area is included within Enclosure 9. Although several seams occur within the Unit I stratigraphy of Tenas Creek most are thin and not of economic significance. Three seams however, currently identified as c-seam, 1-Upper seam, and 1seam, are consistent in nature and form the mineable component of the Tenas Creek resource. Cross-sections through the area, as referenced on the area geology map (Enclosure 20), are included as Enclosure 23.

#### 3.4.6 Cabinet Creek Area

Field mapping was undertaken in the Cabinet Creek area in 1994. Outcrops were found to exist, almost exclusively within the deeply incised drainage systems of the area, specifically those of Cabinet and Webster Creeks. Although outcrops are dominated by volcanic rock exposures, some coal measures were encountered, particularly at lower elevations along the drainage systems. The area appears to have been affected by considerable structural stresses, as faulting and variability in structural orientation, is apparent.

#### 3.4.7 West Tenas Creek Area

The West Tenas Creek area, explored by reconnaissance exploration drilling in 1994, currently has a drill-hole spacing of 750 to 1000 metres. Drilling to date indicates that most of the area is underlain by volcanics and volcaniclastic sediments, presumably of the Hazelton Group. These basement rocks are, in turn, overlain by thick accumulations of Tertiary sands and gravels up to 165 metres in thickness. No coal-bearing stratigraphy has been intersected to date. The exception is within CL3880, which includes a segment of the Telkwa River which is proximal to known coal measures found within the MCL Whalen Freehold Block.

The poorly consolidated Tertiary overburden blanket remains thickest near the Tenas Creek drainage, thinning westerly to less than 12.5 metres near the western property limits. Field mapping within a deeply incised unnamed creek at the western limits of the property has confirmed the presence of volcaniclastic sediments below a shallow mantle of overburben.

#### 3.4.8 Tailings Pond Investigation Site

Work conducted on the tentative tailings pond location was limited to the 1993 exploration program when surface geophysics and drilling were competed over the affected area. No significant coal measures were intersected by drilling in the study area, which is believed to contain the stratigraphic section which underlies the #1 Seam. Surficial geophysics, as well as shallow drilling, has also confirmed the presence of narrow Cretaceous dikes which disrupt the normal stratigraphy of the area. These dikes intersect bedrock at high angles and are presumably related to similar dikes identified along the banks of Goathorn Creek near the current location of the core storage facility.

#### 3.4.9 Northwest Area

No additional work was performed on the Northwest Resource Area in 1993 or 1994. The reader is referred to the 1992 Geological Assessment Report for specifics of the area and a summary of work completed to date. The evaluation of coal quality for the 1993/94 exploration programs is based upon the analytical results of core obtained from diamond and rotary drill-holes. The primary purpose of the coring programs was to obtain sufficient samples of significant coal seams for reliable determinations of the raw and clean quality characteristics of the Telkwa Coalfield. Analytical data received in 1993 and 1994, as well as that from previous years' analyses, have been compiled and are summarized for the Pit #7, Pit #8, Whalen Block and Tenas Creek resource areas (Enclosures 12,17, 19 and 22 respectively).

Specific lab analyses were performed by Loring Laboratories Limited of Calgary, Alberta. Most samples collected were representative of selected coal lithologies, although some seam roof, floor and parting lithologies were also collected and subsequently analyzed. Specific analyses performed were completed in accordance with the coal quality flowsheet provided as Figure 4.1.

Coal in the Telkwa Coalfield varies from High Volatile A bituminous to semi-anthracite by the ASTM classification of coal rank. The vast majority of the area coals, however, are a High Volatile A bituminous product with RoMax vitrinite values generally ranging from 0.80 to 1.00 percent. Within the coal measures of the Skeena Group sediments, observations are that, coal rank generally tends to decrease slightly for coal units situated higher in the stratigraphic column. Localized occurrences of medium-volatile and semi-anthracite coals are thought to have resulted from either post-Cretaceous heat sources, deeper burial and subsequent uplift of some coal-bearing units, or from localized higher heat flux from the pre-Cretaceous basement (Ryan, B.D., 1992). Increases in coal rank have been observed in coals situated at close proximities to the Tertiary intrusive on the northern resource areas as well as some coals within the Cabinet Creek area.

\* on selected samples only.

Figure 4.1

4.1 QUALITY CHARACTERISTICS

Coal quality parameters have been determined from core samples recovered since 1979 from each of the resource areas identified thus far in the Telkwa coalfield. The results presented in this report represent a compilation of all analytical results thus far accumulated within resource areas Pit #7, Pit #8 and Tenas Creek. A compilation of analytical data established to date for the Pit #3 resource area is not included in this report as the results of the five additional drill-holes completed in 1993 did not significantly alter the existing Pit #3 database. The reader is referred to previous years' Assessment reports for coal quality details specific to the Pits #1 to #6 resource areas as well as Northwest Area. Composite analytical results for the 1993 Pit #3 drill-holes, however, are presented within Enclosure 24.

Analytical results of all ply samples recovered in 1993 and 1994 are presented within Enclosure 25 while compiled analytical results for seam composites are available for each area, providing details for each drill-hole, within Enclosures 12, 17, 19 and 22.

Analytical quality data resultant from core extracted in 1993 and 1994 have provided additional information to the existing Telkwa seam quality database. Raw ash values for main seams vary widely as might be expected, ranging from 7.85% to over 50.00%. A similar variability exists with respect to the raw sulphur contents of individual seams, with values normally ranging from 0.30% to 7.77%. It has been observed, however, that although the sulphur contents between different seams within the statigraphic column may vary, seam-specific values remain relatively consistent throughout the extent of the field. In contrast, volatile matter, fixed carbon and calorific values normally remain consistent between all Telkwa seams. The exception is within the #1 Seam package of Tenas Creek which characteristically exhibits slightly lower volatile matter percentages than do all other seams in the Telkwa stratigraphy. This is likely due to a slight increase in coal rank for seams located in the lowermost part of the Telkwa stratigraphy, specifically those of Unit I.

- 42 -

5.0

Quantities of in-situ coal have been determined from drill-hole seam intersection information gathered between 1979 and 1994. Specific resource areas have been identified, each of which represents an independent coal deposit within the limits of the Telkwa Coalfield. Each possesses unique characteristics with respect to deposit geometries and all target the coal measures of either Unit I or Unit III.

Coal resources prepared for this report have been classified according to the Standardized Coal Resource/Reserve Reporting System for Canada compiled by the Geological Survey of Canada (1989). Due to the nature of the Telkwa deposit, the resource areas identified thus far within the coalfield have been classified as *complex* geological deposits. As a result the drill-hole density which currently exists allows the Pit #7 and much of the Pit #8 coal resource to be classified as *measured*, while the Pit #3 area is considered *indicated to measured*. The Tenas Creek prospect has been classified as *indicated*, and still requires additional work to fully establish field limits and deposit geometry. The Whalen Block also requires additional work and has an *inferred to indicated* resource.

#### 5.1 RESOURCE CRITERIA

It is the intent of this study to report the total quantity of significant coal occurring within resource areas identified or further delineated by 1993 and 1994 exploration activities. While this report specifically details the Pit #3, Pit #7, Pit #8, Whalen and Tenas Creek Resource areas, in-situ geological reserve estimates for all Telkwa resource areas are provided on Table 5.1. Quantities reported consider only those seams which are of technically recoverable thickness, and does not consider depth of burial.

Resource estimates have been prepared based upon drill-hole seam intercept information established from geophysical log signatures. Resource areas for which geological computer models were generated include Pit #3, Pit #7 and Pit #8. As

- 43 -

such, total in-situ reserves were determined for these areas via computer modelling software. For the Tenas Creek and Whalen areas, resource estimates are based upon simpler, more direct measurement methods.

Table 5.1

Estimated In-situ Geological Coal Reserve; Telkwa Property

	Resource Area		Geological Reserve (M. tonnes)			Confidence Level

For the Tenas Creek and Whalen areas average seam thickness values were calculated and subsequently the surface area that each seam occupied was measured for each area. The resultant reserve estimates for the Whalen and Tenas Creek resource areas are based upon the following formula:

R = A x Th x SG

where R = Coal Resource (tonnes).

A = Area occupied by a particular seam (m2).

Th = average seam thickness for a particular resource area (m).

SG = the Specific Gravity of a particular seam (g/cm3 = t/m3).

#### 5.1.1 Pit #3 Reserve

The Pit #3 resource area was computer modelled via Eagle Mine Modelling software in 1984 by Shell Canada Ltd. Since acquisition of the property by Manalta Coal Ltd. in 1992 there have been verifications of the Model although to date the area has not been remodelled into a system currently maintained by Manalta.

Exploration drilling completed in 1993 by Manalta in the Pit #3 area did not result in significant changes to the current geological interpretation of the area. As such, in-situ reserve estimates were not regenerated and currently remain at 12,860,000 tonnes.

#### 5.1.2 Pit #7 Reserve

A computer model was generated for the Pit #7 resource area via the Lynx Mine Modelling System in 1992 by Manalta Coal Ltd.. Additional drilling completed in the area in 1994 did not alter the deposit, and consequently the geological model, significantly.

- 46 -

Only seams which attained potentially mineable thickness were modelled, and thus ultimately considered within the reserve calculations of the Pit #7 resource block. Criteria for seam selection was based primarily upon seam thickness; generally seams which exhibited thicknesses of 0.50 metres or greater were included in the volume calculations. Partings with thicknesses exceeding 0.30 metres were considered separable and were not included as part of the seam package. Seams utilized in the reserve calculations, which are equivalent to those modelled, include:

- Seam 2
- Seam 3L
- Seam 3U
- Seam 4
- Seams 5 and 5R
- Seam 6L
- Seam 6U

Seams overlying the #6 coal package were not considered as they were intersected only by one drill-hole and are not adequately represented within the field. The total in-situ coal reserve thus calculated for Pit #7 is 4,327,000 tonnes.

#### 5.1.3 Pit #8 Reserve

Like the Pit #7 area the Pit #8 resource area was modelled via the Lynx Mine Modelling System in 1992. Due to additional drilling in the area in 1993 the Model was subsequently updated to incorporate the additional data.

Pit #8 represents a more complex geological deposit than Pit #7, consisting of two main fault blocks and several smaller fault zones that exhibit minor displacement. In addition the Pit #8 resource area is considerably larger, within which the entire Unit III coal package is well represented. Criteria utilized for reserve estimate calculations are equivalent to those of Pit #7. Seams considered in the reserve calculations, which are equal to those which were modelled, include:

- Seam 2

- Seam 2L where present in significant thicknesses .

- Seam 3L and 3U

Seam 4

- Seam 4U when significant thicknesses were attained
- Seam 5 (which splits to become 5U and 5L westward)
- Seam 5ex where present in significant thicknesses
- Seam 6L and 6U
- Seam 7 in areas where thicknesses met the desired criteria
- Seam 8 in areas where thicknesses met the desired criteria
- Seam 9 in areas where thicknesses met the desired criteria

The reserve estimates are inclusive of all modelled coal seams within the current limits of geological control. Seam extrapolations extend southeastward as far as the Telkwa River valley incision where they are believed to fault terminate. The total in-situ coal reserve thus far established for the entire Pit #8 resource area is 18,499,000 tonnes.

#### 5.1.4 Whalen Freehold Block

Drill-hole seam intersection summaries for the Whalen Block are found within Enclosure 19. Seam surface areas were planimetered from the area geology map (Enclosure 18). Significant folding has not been observed within the area although normal faulting is suspected. Bedding dips average 22 degrees in a northeast direction.

The total in-situ coal reserve for the current explored limits of the Whalen resource area has been estimated at 8,634,000 tonnes for all seams considered mineable. Additional work is considered necessary to further delineate field limits, deposit geometry and ultimately bring the coal reserve to a measured level.

#### 5.1.5 Tenas Creek Area

The Tenas Creek resource area was drilled in 1993 and 1994 allowing field limits to be crudely established for the area. The current level of drill-hole control in Tenas Creek allows its coal reserve classified as indicated.

Tenas Creek drill-hole seam intersection summaries are provided within Enclosures 21 and 22. An average specific gravity of 1.43 was used for the #1 Seam, based upon analytical results from the core-holes completed in the area. Bedding orientations throughout most of the Tenas Creek deposit range from 9 to 22 degrees, dipping northeasterly.

The total in-situ coal reserve identified for Tenas Creek Area is 27,366,000 tonnes, based upon the 3 potentially mineable seams; c-seam, 1U-seam and 1-seam. Additional work is required to fully delineate field limits, establish the deposit geometry, and determine recoverable coal quantities.

Details of costs incurred during the 1993 and 1994 exploration programs are provided within the Cost Summary Report (Enclosure 26). The summary presented represents the total expenditures to date relating to the Telkwa Project 1993/94 exploration activities.

The Skeena Group sediments of the Telkwa Coalfield is an erosional remnant of Lower Cretaceous sedimentary rock deposited along the southern flank of the Bowser Basin. Throughout the Lower Cretaceous sedimentation occurred during which time deposition was influenced by two regressive / transgressive episodes. As a result the stratigraphic sequence is divisible into four lithostratigraphic units, Units I through IV. The lithologies within Units I and III are representative of the regressive episodes and, in turn, the periods of significant peat development in the Telkwa area. The coals within Unit I, collectively referred to as Coal Zone 1 are separated from the Unit III coals by as much as 140 metres of mainly marine sediment. Coal seams #2 through #11, represented in Unit III, collectively contribute 20.5 metres of coal to the Unit's 85.0 metre average thickness.

Since deposition the Skeena Group sedimentary package has been modified by faulting and minor folding resultant from continental stresses that persisted throughout much of the Upper Cretaceous and Tertiary. In addition, during the Eocene of the Tertiary Period, an igneous body intruded the Skeena sediments, further disrupting and faulting the sedimentary package. As a result much of the area is characterized by high angle faulting, breaking the area into a mosaic of structural blocks that have been rotated and tilted into a variety of orientations. Each of the resource areas identified to date are representations of such fault blocks.

Several resource areas have been identified in the Telkwa area and since the early 1900s the area has been sporadically mined, exploiting the Unit I and Unit III coals. It was not until the late 1960s, however, that drilling as a means of identifying potential resource areas was utilized. Between 1979 and 1989 Shell Canada/Crowsnest Resources completed several exploration programs, completing 263 drill-holes and highlighting several resource areas, most of which are located on the south side of the Telkwa River.

The Telkwa Property coal licences have been held by Manalta Coal Limited since May 1st, 1992 and since that time Manalta has completed three exploration programs on the property. While several areas of potential economic interest were identified by the

7.0

- 51 -

property's previous owners, 1993/94 exploration activities were focused on further delineation of the Pit #7, Pit #8 and Tenas Creek resource areas, and reconnaissance exploration of the Tenas Creek West and MCL Whalen Freehold areas. Between the two annual exploration programs Manalta Coal completed 110 drill-holes and 21 kilometres of surface geophysics. Much of work undertaken by Manalta in 1993/94 was completed on the south side of the Telkwa River in the Tenas Creek area. Coal samples were collected from all cored drill-holes for subsequent analysis as were rock samples from representative cores for ARD testing.

The vast majority of the Telkwa area coals explored to date are a High Volatile A bituminous product by ASTM classification of coal rank. Medium Volatile bituminous as well as occurrences of semi-Anthracite coal are also known to exist. While the majority of Telkwa coals are relatively consistent with respect to raw calorific value, volatile matter and fixed carbon values, variations in raw ash and sulphur values occur between seams. Sulphur content variations between some seams is attributed to periodic infiltrations of marine water into the developing peat swamp, while inundations are thought to have terminated development of some of the coal seams.

Resources calculated for the Pit #7 and Pit #8 Resource Areas by Manalta Coal Limited were completed using computer models constructed via the Lynx Mine Modelling system. For the Tenas Creek Area manual methods for resource estimates were utilized. Estimated in-situ geological coal reserves for the five resource areas detailed in this report total 71.69 million tonnes. In-situ reserves for all resource areas identified thus far within the Telkwa Property limits are estimated at 92.52 million tonnes.

CONCLUSIONS

Significant reserves of High Volatile A bituminous coal have been identified within the Telkwa Coal Property limits currently held by Manalta Coal Limited. While the primary value of Telkwa coal is as a thermal product, some of its properties allow it consideration as a low grade coking coal. The coal reserve identified thus far within the property licences is represented by the coals associated with Unit I and Unit III, most of which has been identified within resource areas Pit #3, Pit #7, Pit #8, Northwest Area and Tenas Creek.

The coal reserve identified to date is known to lie within individual fault blocks, or Resource Areas, each with independent field limits and deposit geometries. Results from the 1993/94 exploration programs have aided in further definition of the geology of the Tenas Creek, Pit #7 and Pit #8 resource areas, providing additional coal quality information and better understanding of deposit geometries. While the structure encompassing the Pit #7 and #8 resource areas are closed, Tenas Creek field limits have not yet been established at its southeastern end and as a result additional exploration in this area is required. The resource areas identified as Whalen Block and Tenas Creek West were previously unexplored and, in 1993/94, were identified and partially delineated by the years' exploration activities. Additional exploration in the Whalen Block is required to fully evaluate its geometry and resource potential.

#### 1. DRILLING PROGRAM

A total of ten test holes were drilled in the tailings pond area at the locations shown in Figure 2. A diamond drill with a tricone bit and water was used to drill to bedrock to a maximum of 8 m. Classification of the unconsolidated overburden was based on observations of the colour of the return water, gradation and consistency of the drill cuttings, penetration rate, drill vibration, and drilling difficulty. The results of the test holes are presented in Table 1. Reference should also be made to the nine test pits excavated in the tailings pond area as part of the 1989 investigation reported in 1990 by PEL. The test pit locations are shown in Figure 1.

#### 2. GEOPHYSICS PROGRAM

### 2.1 INTRODUCTION

The goal of the geophysical investigation was to describe the surficial geology as it pertains to the suitability of the location for a tailings pond. Specifically, the objectives of the survey were to describe:

- unconsolidated overburden thickness and characteristics;
- bedrock characteristics; and,
- depth to groundwater.

Conditions were assessed by means of the following methods of geophysical investigation: electrical conductivity, magnetometer, very low frequency electromagnetics, DC resistivity, and seismic refraction.

#### KI93-3773-3 APPENDIX I, TAILINGS POND SITE INVESTIGATION

#### 2.2 FIELD METHODS

#### Grid Layout

Thirteen approximately north/south lines were flagged and cut across the survey area (Figure 2). The lines were spaced from 50 to 100 m apart, and varied in length from about 400 to 1,700 m, for a total of approximately 19 km of cut line. Coordinates along each line were chained and flagged every 20 m. Geophysical field data collection was spatially referenced to these flagged coordinates. Several points along each line were subsequently fixed using GPS (Global Positioning System) and standard surveying techniques as performed by a surveying contractor. These fixed points were then used to place the geophysical survey lines onto a UTM (Universal Transverse Mercator) coordinate system. The baseline for all the cut lines was the road at the southern boundary of the site.

#### **Terrain Conductivity Surveys**

Terrain conductivity is defined as the bulk electrical conductivity of the subsurface. Two terrain conductivity devices were used, the Geonics EM31 and EM34. For low terrain conductivity environments (in contrast to sulphide deposits, for instance), these systems are superior to other induction methods in that they digitally output a value of a physical property, terrain conductivity. The purpose of areally mapping terrain conductivity was to permit tentative description of overburden and perhaps bedrock lithology.

The EM31 and EM34 are similar in their basic theory of operation, but differ in their respective depths of investigation. Generally, the depth of investigation of an electromagnetic (EM) device is controlled by:

- The transmitter/receiver intercoil spacing,
- The transmitter frequency, and
- The dipole (or coil) orientation.
The EM31, with an intercoil spacing of 3.7 m, has a depth of investigation of 6 m in the vertical dipole mode. The lower frequency EM34, when operated in the horizontal dipole mode with a 20 m intercoil spacing, has a depth of investigation of 15 m.

Metals are generally excellent conductors. Buried metal such as pipelines, therefore, may significantly increase the terrain conductivity. Terrain conductivity devices, however, are designed to measure relatively low values of conductivity; even a brine saturated soil will have a conductivity far less than a steel pipe. In an extremely conductive environment, the response of terrain conductivity devices is no longer termed as linear. For this reason, pipelines may appear as a mixture of positive and negative terrain conductivity anomalies, a physical impossibility, but a diagnostic indication of buried metal or a source of electromagnetic noise.

EM31 data were collected on all lines, with a station spacing of 5 m. EM34 data were gathered on the eastern two-thirds of the site, using a station spacing of 20 m.

### Magnetometer Survey

A total field magnetometer measures the intensity of the earth's magnetic field in units of gammas. Sedimentary rocks are generally non-magnetic; igneous rocks are usually moderately to highly magnetic due to their high magnetite content. Oxidation and reduction reactions in faults and fractures may also produce mineral alterations which appear as magnetic anomalies. Hence, shallow sedimentary/igneous contacts or igneous intrusions should appear as significant changes in the total field measurements. The objective of the magnetometer survey was, therefore, to differentiate volcanic from sedimentary bedrock, and perhaps locate faults, fractures, and dykes.

The Telkwa survey was performed with a GSM-19 Overhauser memory magnetometer. The GSM-19 can operate simultaneously with a Very Low Frequency EM (VLF) instrument, thus saving an additional field excursion. Magnetic data were gathered along nine lines spread across the site. A station spacing of 20 m was used.

### KI93-3773-3 APPENDIX I, TAILINGS POND SITE INVESTIGATION

#### Very Low Frequency EM (VLF)

VLF mapping operates on the same principles as other EM mapping techniques. Induced secondary magnetic fields are set up within subsurface electrical conductors such as saturated fractures. The in-phase (dip) and out-phase (quadrature) components of the vertical component of these secondary fields are measured in percentages of the transmitted EM field. Across a conductor's midpoint the dip component "crosses over" from positive to negative percentages. The sharpness of a cross-over depends on a conductor's geometry, depth, conductance, and the transmitted EM field's azimuth and frequency. Unlike the EM31 and EM34, the VLF is only a receiver. The EM field is transmitted from submarine communication towers over a distance of hundreds or thousands of kilometres.

The survey objective was to map geologic lineaments including fractures, faults, and sedimentary/igneous contacts. For these lineaments to be mappable, they must have a significant conductivity contrast due to mineralization, increased porosity, or clay infilling.

The GEM Systems VLF unit was mated to the magnetometer so that the two surveys could be performed in a single site tour. Although the VLF can simultaneously tune into three VLF transmitters from three different azimuths, only the signal from Cutler, Maine, was of sufficient strength to be of use. VLF data were gathered along nine lines spread across the site. A station spacing of 20 m was used.

### **DC Resistivity Soundings**

Resistivity soundings are performed by moving an outer pair of current electrodes about an inner pair of voltage electrodes centred over a fixed point. The further apart the current electrodes are placed, the deeper into the earth the current flows. If one measures the amount of current passed through the earth from a surface power source, the resultant voltage across the two inner electrodes, and the placement locations of the electrodes, then the resistivity of the earth over a specified volume can be estimated. This volume will vary with the geometry of the electrode placements. As a very general approximation, the depth of investigation of resistivity techniques is about equal to half the current electrode spacing (usually noted as AB/2).

# KI93-3773-3 APPENDIX I, TAILINGS POND SITE INVESTIGATION

The advantage of resistivity over conductivity methods is that the former can provide relatively detailed electrical measurements versus depth. The objectives of the resistivity surveys, therefore, were to map changes in overburden with depth at a few locations, and to estimate the depth to bedrock.

The instrument used was the ABEM Terrameter SAS 300C. It is particularly well adapted to remote field surveys as the transmitter is very compact and has a low power consumption.

Seven resistivity soundings were performed. Their locations are overlayed on the EM31 plot (Figure 2).

#### Seismic Refraction

Seismic refraction investigations involve the measurement of the travel time of acoustic energy in the subsurface with the goal of mapping the depth to, and velocity of refractors (high velocity subsurface layers). Successful seismic refraction investigations can provide very accurate depths to bedrock and detailed profiling of bedrock relief. Igneous rocks will generally have much greater compressional wave velocities than sandstones and shales, and therefore will be easily distinguishable as bedrock refractors.

A 24-channel Bison 7024 engineering seismograph with 40 Hz geophones was used. A 16 lb. sledge hammer was used as the energy source. A single line of five overlapping spreads was shot. A geophone spacing of 1 m was used, for a total line length of 108 m. The line was run along the road at the south end of the site, with the midpoint of the line in proximity to drillhole #2 (see Figure 2).

The Generalized Reciprocal Method of seismic refraction data collection and processing was used. Seven records were plotted for each spread, including off-end, end, quarter-spread, and mid-spread shots. Using this technique, a depth to the refractor can be determined below each geophone.

# 2.3 RESULTS

### Terrain Conductivity Surveys

EM31 and EM34 data are plotted in Figures 2 and 3. Interpretations are summarized in the composite plot of Figure 2.

A few general trends can be observed. The EM31 data indicate that conductivities increase from west to east. The conductivity range of 0 to 10 mS/m (blue to green) observed in the west is probably due to a combination of shallow volcanic bedrock, coarse-grained colluvium, and areas of elevated relief and consequently greater depth to groundwater. EM31 conductivities of 10 mS/m or less are typical of clean sands and gravels with little silt and little, if any clay. Moving east toward the marsh, and south toward the proposed plant site, shallow conductivities increase to the range of 10 to 20 mS/m (light green to yellow). These conductivities are typical of silty sands and silts, with little to some clay. From the marsh eastward, EM31 conductivities increase to the range of 20 to 45 mS/m (orange to pink). This range represents an increasing percentage of fines. Conductivities exceeding 30 mS/m probably indicate silt to silty clay till or lacustrine deposits.

The alternating EM31 conductivity highs and lows running parallel to the pipeline right-of-way are due to a buried pipeline. Similarly, the north/south and east/west conductivity highs observed in the southeast corner of the EM34 plot are also due to buried pipelines.

EM34 conductivities generally range from 10 to 20 mS/m over the same area in which the more shallow looking EM31 conductivities range from 20 to 45 mS/m. This suggests that the overburden materials become increasingly clean with depth. Using the drilling information as a guide, it appears that the EM31 is responding largely to materials from surface to a depth of 2 to 4 m, while the EM34 is responding to materials below this depth. EM34 conductivities do increase slightly in the northern 400 m of the surveyed area, where they fall in the range of 15 to 30 mS/m.

#### Magnetometer and VLF Survey

Total field magnetic data are presented in the colour contoured plot of Figure 4. Clearly, there is a significant change in the magnetic character of the bedrock moving toward the east, and occurring approximately along the meridian 621,000 E. Observed outcrops, drilling investigations, increased relief, and increased conductivities suggest that bedrock material to the west is of volcanic origin. It is believed that the volcanic/sedimentary contact can be roughly defined by the 57,540 gamma contour (blue zones). The precise interpretation of this contact is difficult without a better understanding of the general geology of the area. It is unlikely that the contact is sharp (fault-like or the edge of an extrusive body) as the contour lines are widely spaced. It is more likely that the contact represents an increased thickness of sedimentary rocks over volcanic rocks. As overburden materials and sedimentary bedrock are generally indistinguishable using magnetics, it is possible that even in the western portion of the surveyed area, volcanic extrusives may be below shales and sandstones.

In several areas, total field contours are tightly spaced and pod-like (e.g. at test pit #4, west and south of test pit #9, the northwest corner of the survey). Some of these pods line up in roughly east/west linear trends. A possible interpretation of these lineaments is that they are igneous dykes.

Several of these lineaments may be defined by the VLF inphase data of Figure 5. The indicated dykes have been highlighted, taking into account both VLF inphase cross-overs and the magnetic data.

Unfortunately, the VLF data are relatively noisy. This is largely due to the great distance from the VLF transmitter used located at Cutler, Maine, USA, and the difficulty of laying perfectly straight cut lines through the rough terrain at the site.

The booming VLF and multiple magnetic anomalies in the southeast corner of the surveyed area (south of test hole #4) are due to a buried pipeline.

# KI93-3773-3 APPENDIX I, TAILINGS POND SITE INVESTIGATION

# **DC Resistivity Soundings**

While DC resistivity soundings did provide valuable information supporting the overburden data gathered in the EM surveys, the soundings did not identify the overburden/bedrock contact. The electrical properties of the overburden and bedrock are too similar to be distinguished.

Appendix I displays the results of the seven resistivity soundings. Two plots are presented in each figure. The first plot presents the acquired field data on a log-log plot of apparent resistivity (resistivity values measured at surface versus the "true" resistivity of an actual lithologic feature) versus the half-spread current electrode spacing. Increasing electrode spacing indicates increasing depth of investigation.

A curve lies approximately over each data set. The curve was created from a geoelectric model depicted in the second plot. All layers are modelled as being horizontal and laterally continuous, a necessary assumption that may be a crude approximation.

Immediately evident in each of the seven models is an inability to define the overburden/bedrock contact. This can probably be attributed to a lack of a significant resistivity contrast between the overburden materials and the bedrock. As each of the soundings was carried out to a half-spread of 50 m, the depth of investigation probably reached well into the bedrock. If it is assumed that the resistivity of the igneous bedrock greatly exceeds that of the unconsolidated overburden, the resistivity soundings are probably a good indication of sedimentary bedrock existing to a depth of at least 30 to 50 m beneath each sounding.

Conductivity and resistivity are analogous in that conductivity is the inverse of resistivity. The units of conductivity are mS/m (milliSiemens per metre), and the units of resistivity are ohm-m (ohm-metres). To convert conductivity readings in mS/m to resistivity readings in ohm-m, one simply divides the conductivity readings into 1,000. For instance, 20 mS/m is the equivalent of 50 ohm-m.

Modelled resistivities fell in the range from 20 to 600 ohm-m (1 to 50 mS/m); the predominant range was 50 to 100 ohm-m (10 to 20 mS/m). These observed ranges of resistivity correspond to the conductivities measured by the EM34.

The data are generally scattered, with relatively poor fits to the least square curves. This is not due to instrument noise, but is an indication that the assumption of horizontal, lateral continuity of beds does not necessarily hold. The drilling indicates that considerable heterogeneity exists in the overburden materials.

# Seismic Refraction

The seismic refraction data are summarized in Figure 6. What has been mapped is a simple twolayer case of one to two metres of low velocity material (200-300 m/sec) over a refractor of 2,000 m/sec. The first layer is probably dry sand. The second layer is probably saturated sand; the refractor is the water table. No deeper refractor could be observed, even when the seismic source was moved 100 m from the line. This suggests that the saturated overburden and bedrock materials have similar seismic velocities; thus, there is no refraction of the seismic wave front. Although a depth to bedrock cannot be defined, the data indirectly suggest that the bedrock material is sedimentary. Igneous rock would probably have velocities of at least 5,000 m/sec, and therefore would function as an excellent refraction surface.

# **3. INTERPRETATION**

The following discussion is based on the drilling program and interpretation of the different geophysical techniques used to assess the soil conditions across the tailings pond site. The results of the test holes (1993) and test pits (1989) were incorporated as calibration points into the geophysics interpretation.

1. The EM31 data indicate that conductivities increase from west to east. The conductivity range of 0 to 10 mS/m observed in the west is probably due to a combination of shallow volcanic bedrock, coarse-grained colluvium, and areas of elevated relief and consequently greater depth to groundwater. EM31 conductivities of 10 mS/m or less are typical of sands and gravels with little silt and a trace to no clay. It is noted that even minor percentages of silt and clay of 10 to 20 percent or more can result in relatively low levels of hydraulic conductivity.

# KI93-3773-3 APPENDIX I, TAILINGS POND SITE INVESTIGATION

- 2. Moving in a southeast direction from the northwest corner of the area, shallow conductivities increase to the range of 10 to 20 mS/m. These conductivities are typical of silty sands and silts, with little to some clay. From the marsh eastward, EM31 conductivities increase to the range of 20 to 45 mS/m. This range probably represents an increasing percentage of fines. Conductivities exceeding 30 mS/m probably indicate silt to silty clay till or lacustrine deposits.
- 3. EM34 conductivities generally range from 10 to 20 mS/m over the same area in which the more shallow looking EM31 conductivities ranged from 20 to 45 mS/m. This suggests that the overburden materials become less silty with depth. Using drilling information as a guide, it appears that the EM31 is responding largely to materials from surface to a depth of 2 to 4 m, while the EM34 is responding to materials below this depth. EM34 conductivities do increase slightly in the northern 400 m of the surveyed area where they fall in the range of 15 to 30 mS/m.
- 4. Observed outcrops, drilling investigations, increased relief, and increased conductivities suggest that bedrock material in the western portion of the surveyed area is of volcanic origin. The precise interpretation of this contact is difficult without a better understanding of the general geology of the area. It is unlikely that the contact is sharp or fault-like as the contour lines are widely spaced. It is more likely that the contact represents an increased thickness of sedimentary rocks over volcanic rocks.
- 5. Several lineaments defined by the magnetic and VLF inphase data may be indicative of roughly east/west trending dykes.
- 6. Resistivity methods do not appear capable of resolving the overburden/sedimentary bedrock contact. The data indirectly suggest that the bedrock material at each of the sounding sites, to a depth of at least 30 to 50 m, is sedimentary. Modeled resistivities in the overburden fell in a range similar to the observed conductivities as measured by the EM34. The resistivity data are generally scattered, with relatively poor fits to the least square curves. This is probably an indication that the assumption of horizontal, lateral continuity of beds does not necessarily hold. Drilling confirmed that the overburden materials are heterogeneous.

7. Seismic refraction methods do not appear capable of resolving the overburden/ sedimentary bedrock contact. However, the data indirectly suggest-that the bedrock material beneath the seismic line is sedimentary.

                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                      |                                                       |                                                       |
