### **Statements of Author's Academic and Professional Qualifications**

The author of this report, K.A. Komenac, in 1973 received the degree of Bachelor of Science (Geology Major) from the University of British Columbia, and is registered as a Professional Engineer with the Association of Professional Engineers and Geoscientists of the Province of British Columbia. The author has been an employee of Fording Coal Limited at the Fording River Operation since November of 1973 as Assistance Pit Geologist, Exploration Geologist, Senior Exploration Geologist, and since 1989 Senior Geologist.

## Fording River Operations

### Summary Report

#### 2005 Exploration Program

##### I. Introduction

###### 1. General Geography and History

The Fording River Coal property is located in the Fording River and Upper Elk Valleys, approximately 25 kilometres north of Elkford, BC. Access is by paved road north from Elkford along the Fording River Valley, or north along the Elk River Valley via the Forestry Service gravel road or the Kan-Elk Powerline road.

The Fording River minesite is situated within the front range of the southern Canadian Rocky Mountains. At least ten major coal seams, generally greater than four metres thick, are contained in the Mist Mountain Formation of the Kootenay Group.

The Elk River portion of the property was actively explored by the Canadian Pacific Railway Company in the period 1902 - 1908. Until 1947, the property was comprised of 10,276 hectares in 40 Crown Granted Lots. In that year, the holdings were reduced to 2,979 hectares in 15 Crown Granted Lots. In 1967 and 1968, Canadian Pacific Oil and Gas reacquired part of the coal lands which had been abandoned in 1947. An additional nine Coal Licences located at the south end of the property were acquired in 2001. At the present time, the Fording River Property consists of 22,635 hectares, held on seven Coal Leases, 9 Coal Licences, and 15 Crown Granted Lots.

Mining operations which commenced in 1971, have produced more than 182.0 million tonnes of clean metallurgical and thermal coal for markets in North and South America, Africa, Europe and Asia. Of this total, 9.3 million tonnes were produced in 2005.

## 2. Geology

### i) Stratigraphy

The general stratigraphic succession on the Fording River Property is summarized in the following table:

| Period           | Litho-Stratigraphic Units |                         | Principal Rock Types   |
|------------------|---------------------------|-------------------------|--|
| Recent           |                           |                         | Colluvium  |
| Quaternary       |                           |                         | Clay, silt, sand, gravel, cobbles  |
| Lower Cretaceous | Blairmore Group           |                         | Massive bedded sandstones and conglomerates                                  |
|                  | K                         | Elk Formation           | Sandstone, siltstone, shale, mudstone, chert pebble conglomerate, minor coal |
| Lower            | O                         | Mist Mountain Formation | Sandstone, siltstone, shale, mudstone, thick coal seams                      |
| Cretaceous       | O                         |                         |  |
| to               | T                         | Moose Mountain Member   | Medium to coarse grained quartz-chert sandstone                              |
| Upper            | E                         | M F                     |  |
| Jurassic         | N                         | O O                     |  |
|                  | A                         | R R                     |  |
|                  | Y                         | R M                     |  |
|                  | I                         | A                       |  |
|                  | G                         | S T                     | Weary Ridge Member   |
|                  | R                         | S I                     | Fine to coarse grained, slight ferruginous quartz-chert sandstone            |
|                  | O                         | E O                     |  |
|                  | U                         | Y N                     |  |
|                  | P                         |                         |  |
| Jurassic         | Fernie Formation          |                         | Shale, siltstone, fine-grained sandstone                                     |
| Triassic         | Spray River Formation     |                         | Sandy shale, shale quartzite   |
|                  | Rocky Mountain Formation  |                         | Quartzite  |
| Mississippian    | Rundle Group              |                         | Limestone  |

The oldest rocks present on the Fording River property are the Rundle Group limestones, located on the west bank of the Fording River, near the southern property boundary. They are in faulted contact with the Kootenay Group to the west, and unconformable contact with Rocky Mountain Formation quartzites to the north. The latter are best exposed on the eastern slope of the Brownie Creek Valley.

The Fernie Formation shales occur throughout the area, generally along the sides of the valleys on the lower flanks of the mountains. The shales are recessive and, therefore, poorly exposed. The Fernie Formation is in conformable contact with the Morrissey, through the "Passage Beds," which are a transitional zone from marine to non-marine sedimentation.

The Morrissey Formation, which is the "basal sandstone" of the Kootenay Group, is a prominent cliff-forming marker horizon in many locations. On the Fording River Property, the top of the Moose Mountain member (Morrissey Formation) is in sharp contact with #1 or A seam, the lowermost bed of the Mist Mountain Formation.

The Mist Mountain Formation contains all of the economic coal seams, and is the most widely occurring formation on Fording River Property. This economically important formation is an interbedded sequence of sandstones, siltstones, silty shales, mudstones, and medium to high volatile bituminous coal seams. The volatile content of the coal increases up section, with decreasing rank. Lenticular sandstones comprise about 1/3 of the Mist Mountain sediments at Fording River, but very few laterally extensive sandstone beds exist.

The sandstone above and below seam #4 (B) and above #9 (F), are the most persistent units, and are often cliff-forming marker horizons.

The Mist Mountain Formation is generally overlain conformably by strata of the Elk Formation. On the Fording property, this formation is commonly a succession of sandstones, siltstones, shales, mudstones, chert pebble conglomerates and sporadic, thin, high volatile bituminous coal seams. The coal seams are characterized by a high alginate content and referred to as "Needle" coal. The Elk Formation is observed near the tops of the mountains, mainly on the east side of the Elk Valley on the Greenhills Range, and northward to the Mount Tuxford areas.

The top of the Elk Formation marks the upper boundary of the Kootenay Group, which is unconformably overlain by the basal member of the Blairmore Group. This thick bedded, cliff-forming sandstone and conglomerate unit is observed on the upper slopes of Mount Tuxford.

ii) **Structure**

Subsequent to deposition, the sediments were involved in the mountain building movements of the late Cretaceous to early Tertiary Laramide orogeny. The major structural features of the Fording River property are the north-south trending synclines with near horizontal to steep westerly dipping thrust faults, and a few high angle normal faults. Some of the thrust faults probably were folded late in the tectonic cycle.

The formation of the major fold structures began early in the tectonic cycle. In the current mining area, two asymmetric synclines are evident; the Greenhills Syncline to the west, and the Alexander Creek Synclines to the east of the Fording River.

The thrust faulting (ie: the Ewin Pass and Brownie Ridge Thrusts), was probably contemporaneous with the later stages of folding. The intervening anticline was subsequently faulted (Ericson Fault), then eroded.

The Alexander Creek Syncline can be traced from the southern property boundary on Castle Mountain to the northern end of the property on Weary Ridge. The strata of the west limb, on the west face of Eagle Mountain, dips easterly at 20 to 25°, decreasing gradually to zero as the axis is approached. The east limb, however, attains a 20° westerly dip within a much shorter (500m) distance of the axis. This asymmetry is possible due, at least in part, to the influence of the Ewin Pass Thrust which subcrops 600 to 800 metres east of the synclinal axis.

Further to the east, on Brownie Ridge, the strata dips westerly at a mean dip of  $42^{\circ}$ . The Brownie Ridge Thrust, which subcrops near the crest of the ridge, probably contributes to this steepening.

Within the mining area, the axis of the Alexander Creek Syncline plunges to the north at an average of  $4^{\circ}$ . Turnbull Mountain exhibits a localized series of an echelon fold structures, plunging both to the north and south. These subsidiary folds may be related to thrust faulting. From the south end of Mount Tuxford, the synclinal axis continues north-northwest along the base of Mount Veits and into the Elk River Valley near Aldridge Creek.

On Mount Tuxford, the beds exposed are those of the Elk Formation and the overlying (non-coal bearing) Cadomin Formation. The area has not been extensively explored. The stratigraphic sequence of the east limb, in the more extensively explored Mist Mountain strata near Aldridge Creek (Elco property), closely resembles the east limb strata found on Henretta Ridge, ten kilometres to the south.

On the northwest corner of Eagle Mountain, the lower Kootenay-upper Fernie section is the locus for a zone of near horizontal thrust faulting. The effect is to cause a double repetition of the lower coal seams and basal sandstone on the west synclinal limb. This fault zone is synclinal in form, and continuous with the Ewin Pass Thrust zone found the east limb.

The Greenhills Syncline in the mining area, is essentially a "mirror-image" of the Alexander Creek structure. The east limb of the asymmetric syncline dips westerly at  $15$  to  $25^{\circ}$ , except in areas near the Ericson Fault, where  $45$  to  $55^{\circ}$  dips are common. The west limb exhibits much steeper dips; commonly in the  $35$  to  $45^{\circ}$  range. The Greenhills Syncline plunges northward ( $340$  to  $350^{\circ}$ ), at less than  $5^{\circ}$ , then apparently dies out to the north in the area of the Osborne Creek Depression.

The Ericson Fault, which locally runs along the base of the Greenhills Range west of the Fording River, is one of the major regional faults. From south to north, this westerly dipping (40 to 70°) normal fault, brings Mist Mountain strata progressively into contact with Rundle, Rock Mountain, Spray River, Fernie and Morrissey strata. The downthrown block is to the west.

Near the south end of Lake Mountain, the Ericson Fault begins to "splay" into two zones. The main fault runs along the eastern margin of Lake Mountain, and the subsidiary fault runs to the west, and appears to "die out" northward. The steep northward dip exhibited in the Lake Mountain strata could be due to influence from these flanking "splays" of the fault. The flat lying region to the north of Lake Mountain (Osborne Creek Depression area) is completely void of outcrop, and the Ericson Fault has not been traced either through or to the north of this area.

3. **Summary of Work Done in 2005**

20 reverse circulation drill holes were completed for a total of 7,131 metres. Geological field mapping was conducted by staff geologists on Bare Mountain.

Rotary drilling was done by SDS Drilling using an Ingersol Rand TH100 truck mounted rig and a Jaswell 2400 truck mounted rig.

All holes were geophysically logged through the rods using the gamma-neutron method. Holes that remained open after the rods were pulled were logged for hole deviation, and selected holes were logged for gamma-density. Logging was done by Century Geophysical Corporation.

Coal seams encountered by rotary drilling were samples in 0.5m intervals. Representative composite samples for each coal seam encountered in the hole were prepared at Fording's Process Plant Laboratory. Each seam composite was tested for proximate analysis, % Sulphur and Free Swelling Index. Samples from selected seam composites were sent to David E. Pearson and associates for petrographic analysis.

Fording staff laid out the access roads and drillsite locations. Pre-logging was done by Diesel Logging. Road and drillsite construction was done by Tiegen Contractors Inc. Staff surveyors provided the required survey control and drillhole pickups.

The following table shows the drillhole locations with respect to Coal Lease and Licence boundaries:

| <u>Lease / Licence</u> | <u>Drillholes</u>              |
|------------------------|--------------------------------|
| BC Coal Lease #17      | RH # 2824 - 2831 inclusive     |
| Coal Licence #327992   | RH # 2797 - 2802 inclusive     |
| Coal Licence #327993   | RH # 2803, 2804, 2846 and 2847 |
| Coal Licence #328674   | RH # 2848                      |
| Lot 4588               | RH # 2796                      |

## **II Individual Area Programs**

### **1. Southeast Turnbull Mountain**

#### **i) Objective**

Results from an economic analysis of the northeast Eagle/southeast Turnbull region indicated a good potential for additional reserves exists on the southeast flank of Turnbull Mountain. These reserves would extend the current Eagle Mountain reserves an additional 800 metres northward onto Turnbull Mountain.

The objective of the southeast Turnbull drilling program was to provide the fill in geological and coal quality data required to confirm the geological interpretation and economic analysis. The additional drillholes would also bring the drillhole density to within the requirements for reserves designation.

#### **ii) Summary of Work Done**

Eight reverse circulation rotary holes were completed for a total of 2,275 metres. All holes were geophysically logged through the drill rods using the gamma-neutron method. All holes were also logged open hole for gamma density and hole deviation, with the exception of RH #2829m which has caved at 95 metres.

#### **iii) Results and Conclusions**

The 2005 drilling program on Turnbull Mountain intersected seams from 040 up to the 14 seam series. Most of the seams were slightly thicker than anticipated, particularly seams 130, 120 and 100, the most economically important seams in the area. Re-evaluation of this area, with inclusion of the new drillhole information, is expected to confirm the previous economic evaluation, and should lead to reserves additions.

#### **Reference:**

- i) Illustration 2: Southeast Turnbull Exploration Program**

## **2. Castle Mountain**

### **i) Objective**

The objective of the 2005 drilling program was to determine the reserves potential of the recently acquired southwest corner of Castle Mountain.

### **ii) Summary of Work Done**

Seven reverse circulation rotary holes were completed for a total of 2,656 metres. All holes were geophysically logged through the drill rods using the gamma-neutron method and open hole, using the gamma density and hole deviation methods.

### **iii) Results and Conclusions**

The 2005 drillholes intersected seams from the entire Mist Mountain Formation, as well as several hundred metres of Elk Formation (RH #2801) and a repeated Moose Mountain sandstone (RH #8796). Seam thicknesses and strip ratios are similar to those encountered further to the north.

Sufficient information is now available to allow a preliminary assessment of the reserves potential over the entire length of the west flank of Castle Mountain.

Reference:

- ii) Illustration 3: 2005 Completed Exploration Chauncey/Bare Mountain**

### **3. Bare Mountain**

#### **i) Objective**

Bare Mountain was extensively trenched and field mapped by Crowsnest Resources in the early 1980's. Two deep diamond drillholes were also completed at that time, both on the north facing flank. In 2001 and 2002, four reverse circulation rotary holes were completed by Fording River Operations, all on the north flank of Bare Mountain.

The objective of the 2005 drilling program was to determine if the encouraging seam thicknesses and stripping ratios encountered in the holes on the north facing slope continue southward onto the west facing flank of Bare Mountain.

#### **ii) Summary of Work Done**

Five reverse circulation rotary drillholes were completed for a total of 2,200 metres. All holes were geophysically logged through the drill rods using the gamma-neutron method. All holes were also logged open hole using the gamma density and hole deviation methods.

#### **iii) Results and Conclusions**

Results from the 2005 drillholes correlate well with the previous holes drilled on the north facing slope, particularly with the two diamond drillholes completed by Crowsnest Resources in 1981. Seams 11, 7 and 5 are very thick throughout the area, generally exceeding 10m in vertical thickness. True thickness is somewhat less, due to the steep bedding dips that prevail on Bare Mountain ( $60^{\circ}$  or steeper). These thick seams are often repeated throughout the section, by the many thrust faults that affect the area. Strip ratios remain encouraging, in spite of the steep bedding and extensive thrust faulting. Extensive fill in drilling proposed for 2006 will allow completion of an economic evaluation for Bare Mountain.
