DESCRIPTION OF DEPOSIT/DESCRIPTION DU GISEMENT

The formation consists mainly of green schistose amphibolite of Pre-Permian age. These rocks are badly broken and contorted, very much altered and metamorphosed. Outcrops that are thought to be all portions of the same vein, the North vein, occur at intervals for a distance of over 5,000 feet, strike northwesterly and dip to the northeast at angles ranging from 40 to 60 degrees. The vein varies in thickness from 18 inches to 4 feet, and consists mainly of quartz mineralized with argentiferous tetrahedrite, pyrite, chalcopyrite, and galena.

The South vein, from 6 to 10 feet in thickness, dips to the southwest at angles ranging from 50 to 70 degrees. It is composed mainly of quartz containing varying amounts of disseminated galena and chalcopyrite.

HISTORY OF EXPLORATION AND DEVELOPMENT
HISTORIQUE DE L'EXPLORATION ET DE LA MISE EN VALEUR

This property is located on the west shore of Tagish Lake, the claims extending south from Buchan Creek.

The showings were staked in about 1899 by Messrs. Young, Johnson, and Grant, officials of the White Pass Railroad. Development work was carried on until 1902 when the property was acquired by a local Atlin syndicate; this group carried on development work until about 1904.

In about 1913 the property, consisting of 8 claims, the Pansy, Rose, Buttercup, Calder, Primrose, Daisy, Merry, and Daffodil, was acquired by Messrs. Partridge & Egerton.

Development work on the North vein consists of a shallow shaft and a drift adit. On the South vein two drift adits have been run in a short distance.
