INTRODUCTION

The Fernie west-half map sheet (82G/W ½) straddles the Rocky Mountain Trench in southeastern British Columbia. The area is generally rugged, with the Purcell Mountains exposed in the western half of the sheet and the Kootenay Ranges of the Rocky Mountains in the eastern half. The Purcell Supergroup, a thick accumulation of dominantly clastic rocks of Helikian age, forms the core of the Purcell Mountains and is exposed in thrust sheets along the western edge of the Kootenay Ranges. Its base is not exposed. The Purcell Supergroup is onlapped unconformably by Hadrynian rocks at the north end of the Fernie map sheet, and by Cambrian or Devonian rocks in the southern half.

This report, Part A of Bulletin 76, includes 26 measured sections of the Purcell Supergroup, and one section of the overlying Cranbrook Formation. The location of the measured sections are shown on Figure 1 and their extent in the Table of Formations on Figure 2. Part B of Bulletin 76 comprises text, maps, and diagrams describing the stratigraphy, sedimentology, structure, and contained mineral deposits of the Purcell Supergroup in Fernie west-half. It is scheduled for publication in 1986.

FIELDWORK AND ACKNOWLEDGMENTS

This report is part of a field study of Purcell Supergroup rocks in southeastern British Columbia that was initiated in 1976 and completed in 1983. Four 1:50 000-scale maps have been published:

1. Estella-Kootenay King Area, Hughes Range, Southeastern British Columbia (82G/11, 12, 13, 14); T. Hoy (1979),
2. Mount Fisher-Sand Creek (parts of 82G/6, 11, 12); M. E. McMechan (1979),
3. Moyie Lake Area (82G/W); T. Hoy and L. Diakow (1981),

The sections were measured by T. Hoy and L. Diakow with the assistance of M. Fournier, I. Webster, and S. Pattenden. Section 15, the reference section for the Nicol Creek and Van Creek Formations, has been published previously (McMechan, et al., 1980).
