**THE BRITISH COLUMBIA
MINERAL POTENTIAL PROJECT 1992-1997**
METHODOLOGY AND RESULTS

By Ward E. Kilby, MSc, PGeo

GeoFile 2004-2

EXECUTIVE SUMMARY

During the 1990s, British Columbia became the first province or state to complete a comprehensive mineral potential assessment of its jurisdiction, an area of 948 596 square kilometres. This bulletin provides an overview of the methodology used to make that assessment. As well, it documents the results of the assessment and their reliability.

The Mineral Potential project was initiated in 1992 by the Geological Survey Branch of the Ministry of Energy and Mines to meet the need for current regional mineral potential information in support of regional and sub-regional land-use planning. These planning processes had the responsibility to make recommendations on protected areas, as described in the provincial Protected Areas Strategy. As mineral exploration and mining are proscribed in protected areas, it was important that participants in the decision making process be provided with a semi-quantitative assessment of the mineral resource potential of areas under consideration for protection.

Project objectives were three fold:

- Rank the land base of the province by its ability to support economic activity through mineral exploration and extraction.
- Produce results that are credible and understandable by all user groups, to assure the results of the analysis are used in the land-use planning process.
- Incorporate the expertise of the mining and exploration communities.

The study took five years to complete and involved over 30 person years of staff time. It relied on a variety of government databases, including the mineral occurrences (MINFILE), bedrock geology, regional geochemical survey, aeromagnetic survey and company assessment report (ARIS) data. One of the major inputs to the project was an updated digital geological map of the province that drew on the collective expertise of many of the British Columbia Geological Survey staff. It also incorporated new geological mapping by the Geological Survey of Canada. All the mapping results of the mineral potential project and much of the related

data were posted to the web to allow users access to the information.

The Mineral Potential Project developed a methodology that was largely based on the United States Geological Survey (USGS) three-part mineral resource assessments. While the basic assumptions were similar to those made by the USGS, there were several significant differences including the scope of the project, the use of industry experts and the addition of estimates of industrial mineral deposit potential. Estimation workshops were held for each study area in the province so that industry experts and government staff could make probabilistic estimates of expected numbers of undiscovered deposits. Geologists and land use planners examined and applied results from each study area, thus providing a very good review of the methodology used and conclusions reached.

Two regional maps and accompanying attribute information were generated for each of the nine Mineral Assessment Regions. One map was used to illustrate metallic mineral potential and the other industrial mineral potential. The tracts within the region were grouped into 10 classes based on their ranking values to determine their relative importance.

The tract attribute information includes values such as: tract area, number of MINFILE occurrences, value of known resources, value of past production and value of exploration expenditures. Mineral Resource Assessment-generated data for each tract include: the number of potential new deposit discoveries by type, dollar value of commodities in potential discoveries, types of commodities expected to be discovered and ranking of tract relative to the other 794 tracts in the province.

A valuable preliminary product of the whole analysis process is the expert estimation of the number of expected new discoveries of each deposit type in each tract. These values can be displayed on maps as the discovery favourability for a single deposit type across the province.

CHAPTER 1

Access to as large a land base as possible for exploration is critical to the mining industry. However, recent social demands are for a percentage of the land to be excluded from industrial development to preserve its natural character. For the past 30 years government geological surveys have been conducting mineral resource assessments to provide information for planning processes about undiscovered mineral endowments. A segment of the industry argues that it is impossible to predict where most mineral deposits will be found; they declined to participate in the process, arguing that no lands should be withdrawn from mineral exploration. Another segment reluctantly accepts the fact that governments are reflecting the will of the people in creating more parkland; this segment has worked with geological surveys to try to devise the best methodology possible to conduct Mineral Resource Assessments (MRAs), believing that it is essential that the best available estimates are available to ensure that informed land use decisions are made. This report describes the BC methodology and experience.

In 1992 the Province of British Columbia implemented a Protected Area Strategy that stated:

"British Columbia is committed to developing and expanding a protected areas system that will protect 12% of the province by the year 2000 (Province of British Columbia, 1993). The Protected Areas Strategy presents government policy on protected areas and will be used by land use planning processes to recommend land allocations to Cabinet. The target of 12% will be made up of protected areas, including land and freshwater or marine areas that are set aside to protect the province's diverse natural, cultural heritage and recreational values. Protected areas are inalienable: the land and resources may not be sold. They are also areas in which no industrial extraction or development is permitted. No mining, logging, hydro dams or oil and gas development will occur within protected areas".

INTRODUCTION

The Protected Areas Strategy has two goals. The first is to **protect representative examples** of natural diversity in the province and the characteristic backcountry recreational and cultural heritage values of each ecoregion. The second goal is to **protect the special natural, cultural heritage and recreational features** of the province, including rare and endangered species and critical habitats, outstanding or unique botanical, zoological, geological and paleontological features, outstanding or fragile cultural heritage features, and outstanding outdoor recreational features such as trails.

This strategy was initiated in part in response to findings of the World Commission on Environment and Development (Brundtland Commission) and in part to a growing demand for a coordinated land use plan for the province. Canada and many of the provinces agreed with and accepted the challenge of the Brundtland Commission to "protect their diversity of species and ecosystems", calling this a prerequisite to sustainable development. Thus, to truly achieve sustainable development, Canada must "identify and protect a complete range of representative and unique natural areas, wilderness landscapes and wildlife habitats."

In 1992, the Commission on Resources and Environment (CORE) was given legal responsibility to "develop for public and government consideration a British Columbia-wide strategy for land use and related resource and environmental management" (CORE Act, s. 4 (1)). CORE first focused on four regions, which were considered to be high priority areas for protection. These were Vancouver Island, Cariboo - Chilcotin, East and West Kootenays. CORE was disbanded in 1995. Land use planning and the implementation of the Protected Areas Strategy, is now being addressed by various Land and Resource Management Plan groups (LRMPs) for the entire province. This process is ongoing, with numerous LRMP areas in various stages of completion and other areas being considered for this planning process (Figure 1).

In British Columbia there was another impetus for conducting MRAs. A large number of "Statement of Intents" to negotiate traditional

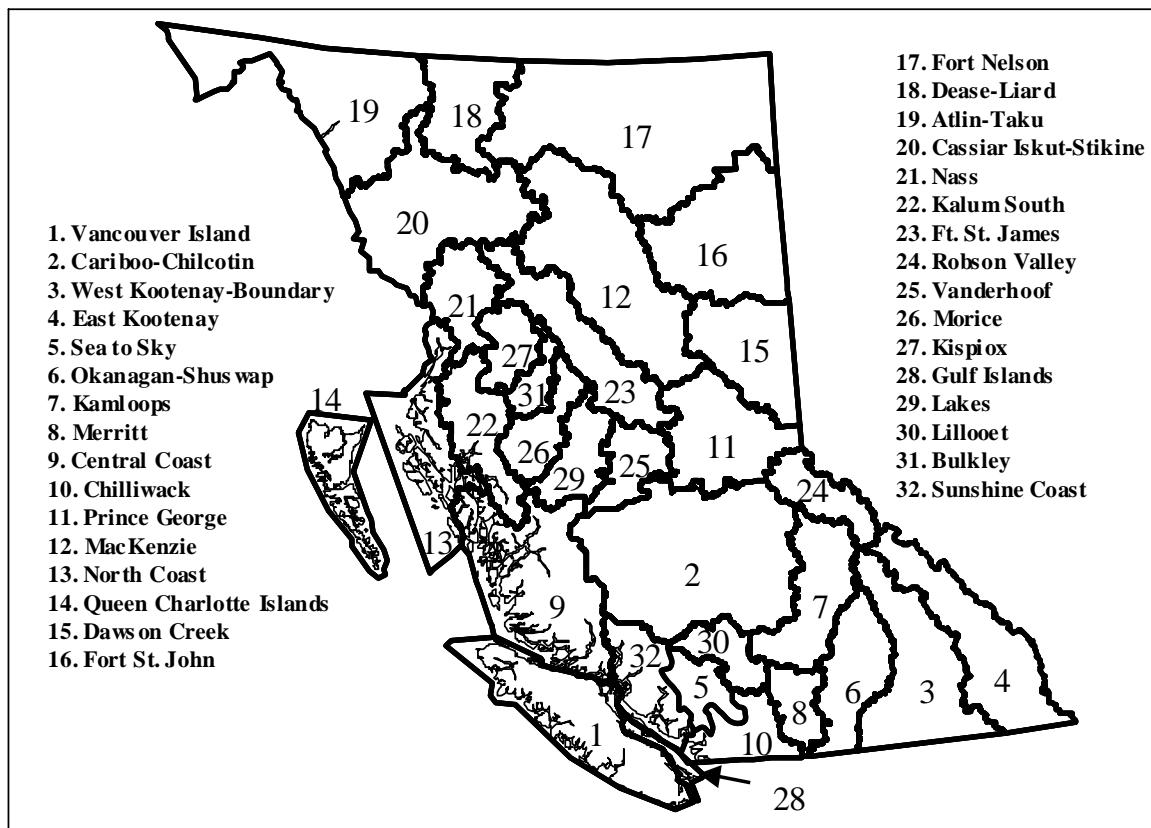

Figure 1. Distribution of the three CORE regions (1,2,3-4) and the distribution of LRMP areas.

territories had been submitted by First Nations to the BC Treaty Commission. The entire landmass of British Columbia is included in at least one of these Statement of Intents. These land use and land valuation processes placed further demands on the Geological Survey Branch to provide the best possible information about known and potential mineral resources in the province (Figure 2).

Early in 1992, the British Columbia Geological Survey Branch of the Ministry of Energy and Mines (earlier, Energy, Mines and Petroleum Resources, and then Employment and Investment) launched the Mineral Potential Project over a 5-year period to develop the information required by CORE. The 9 regions subsequently assessed cover the whole province – some 948 500 square kilometres (Figure 3). The order of these assessments was dictated by the order of the major land use planning exercises. In general, it required about one year for an analysis team to complete the assessment of a region. Up to three assessments were run

concurrently to complete the project within the defined timeframe. The Geological Survey Branch has dedicated in excess of 30 person years to meeting this information requirement. Completion of the assessments in step with the land use planning processes was critical. If up-to-date mineral resource assessments were not available during the planning negotiations, either outdated information would be used, or mineral potential ignored. Prior to this project the last regional assessment of mineral resource potential by the Branch was performed between 1972 and 1981 by a number of authors and published as individual 1:250 000 maps (McCartney, *et al.*, 1974 and see references for maps). These twenty year-old studies provided the best available information prior to this project and planners were starting to reuse them in the modern planning process. The MRAs were only one of more than 20 inventories that were employed in the planning processes. For example several other major information types were: forest values, fisheries values, tourism potential, agriculture potential, presence of critical wildlife

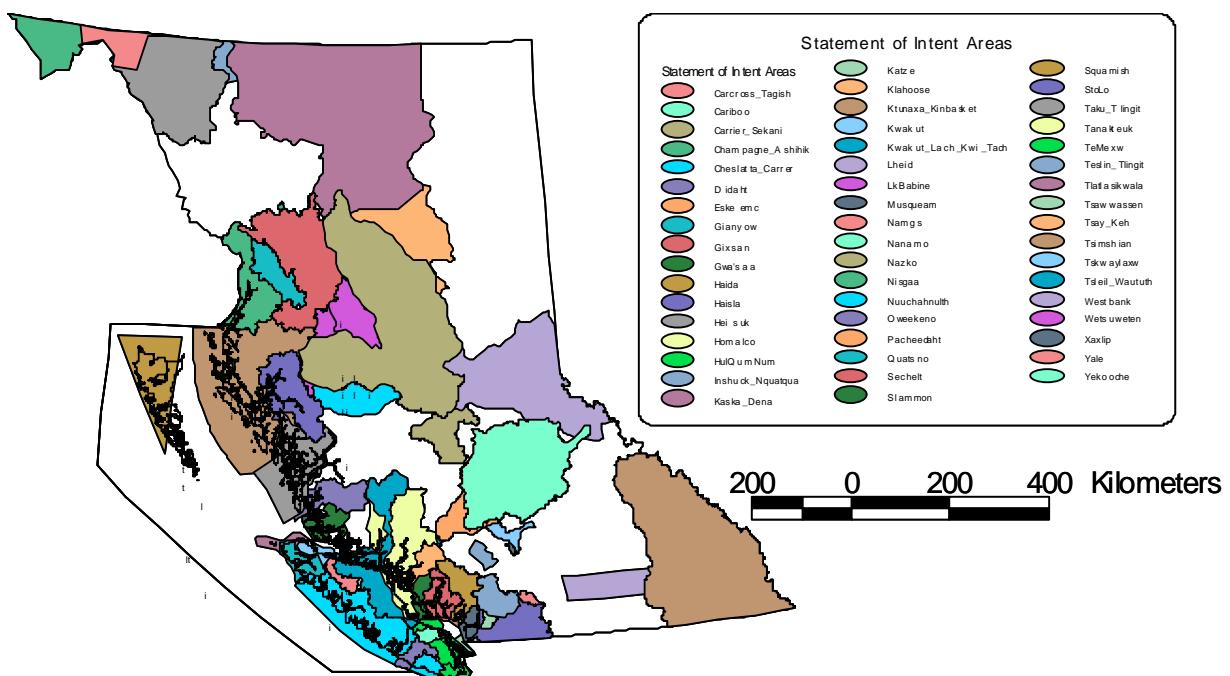

Figure 2. Map showing the distribution of Statement of Intents to enter the treaty negotiation process.

habitat or endangered species, and archeological sites.

The first major task of the Mineral Potential Project group was to determine the type of information that would be useful in land use negotiations and develop a methodology which would best produce this information. A two-day workshop was held to investigate this question (Kilby, 1992). Participants, with recent experience in producing and using Mineral Resource Assessments in Canada and around the world, came from across Canada and the United States Geological Survey. The workshop outlined the current methodologies and discussed their strengths and weaknesses in land use planning. From the workshop it was determined that the MRA products must have the following characteristics:

- be quantitative rather than qualitative
- provide a ranking of the land base
- have major input from experts from the mining and exploration industries
- produce digital GIS-compatible products
- be readily available

Quantitative, easily understood results were desired because the LRMP process involved people with a wide range of technical and non-technical backgrounds who had to consider the MRA results in the decision-making process. In addition, quantitative information can be used in subsequent socio-economic analysis. Ranking of the land base was necessary because the Protected Areas Strategy dictated that a target of 12% of the land area in each region would be protected; double the amount protected previously. A major objective of the Mineral Potential Project was therefore to rank the relative mineral potential of the land base so that planners could easily identify areas with the lowest relative mineral potential during their land use planning.

The mining and exploration industries of BC have built an enormous knowledge base that is not in the public domain. Their involvement and cooperation gave us access to some of this knowledge and also enabled us to familiarize public sector stakeholders with the strengths and limitations of the MRAs. Government dictated production of all information for the land use planning processes in a Geographic Information System compatible digital format. Adherence to

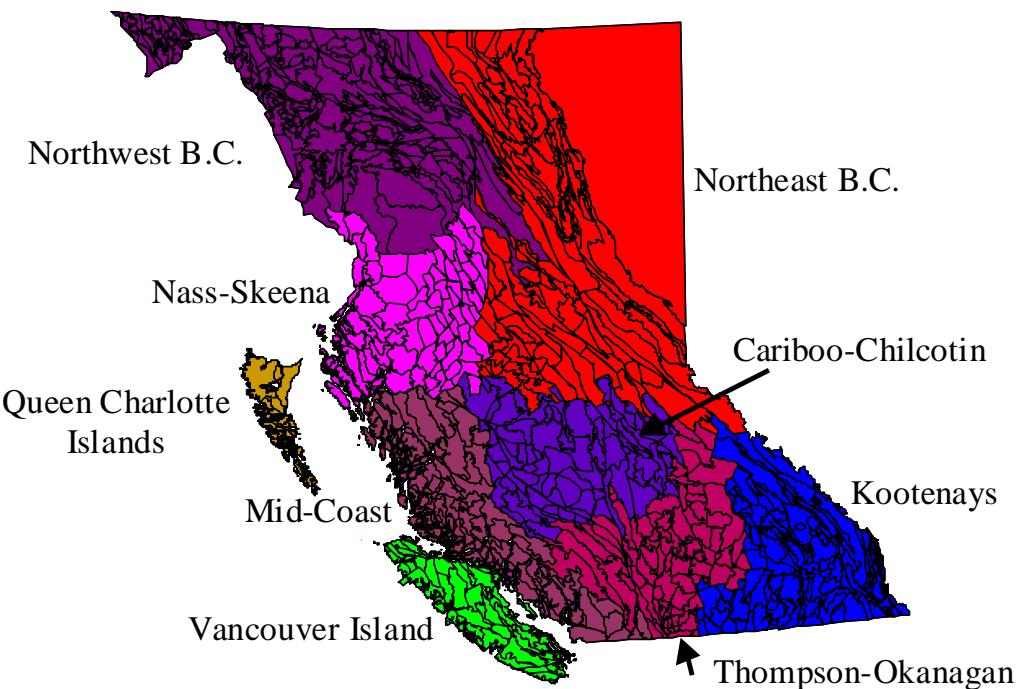

Figure 3. Distribution of the nine Mineral Assessment Regions used in this project.

this policy assured the information was easily incorporated into the analysis systems used by the planners. In addition, storage of the information in digital format provides an opportunity to more easily upgrade the information in the future.

Based on the results of the workshop, a plan for the production of MRAs in BC was developed which was based on the United States Geological Survey's "Three Part Mineral Assessment Methodology" (Singer, 1993). Modifications were made to their procedure to meet the specific requirements of this project. During the life of the project our experiences led to a number of minor adjustments in our initial methodology. The methodology currently used has been applied consistently to all assessment regions, so the results from one region may be compared to the results from a neighboring region. Two slightly different techniques are used to assess metallic and industrial mineral commodities due to their very different dependence on infrastructure and markets (Figure 4). A six-step process is used for the metallic mineral resource assessments:

1. compile geology
2. select mineral assessment tracts
3. tabulate discovered resources and construct deposit models

4. employ a team of industry and government experts to estimate the number of undiscovered deposits by deposit type and tract
5. determine quantities of metallic commodities remaining to be discovered using the Mark3B Mineral Resource Assessment Monte Carlo simulator
6. calculate the gross in-place value (GIPV) of each tract based on the undiscovered and known commodities it contains.

For industrial mineral assessments the first 4 steps are the same. However, instead of using the Mark3B simulator and associated GIPV, a relative ranking of industrial mineral deposit types was employed. All industrial mineral deposit types were given a relative ranking score from 1 to 100 based on their perceived value and viability. This relative deposit value score (RDVS) was used to determine the importance of each tract with respect to undiscovered deposits. The estimates were then blended with the value of discovered industrial mineral deposits to produce the overall industrial mineral tract assessment ranking.

Project Chronology

The Mineral Potential Project ran for five years. During that time a large number of individuals from both industry and government contributed a great deal of time and effort to ensure its successful completion. The following is a brief

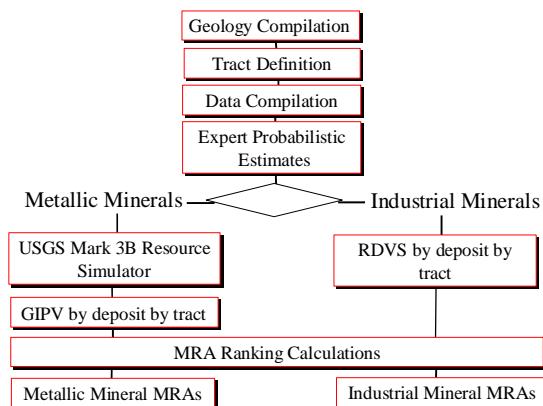

Figure 4. Major steps in the evaluation of the estimates of future deposit discoveries. The process for industrial minerals parallels but differs slightly from that for metallic minerals.

chronology of the project, highlighting the individuals involved, major products produced and other significant events (Figure 5).

In April of 1992 the project began. The first major activity was the Mineral Potential Workshop (Kilby, 1992) which brought together people familiar with conducting MRAs elsewhere, those who would be involved in the British Columbia effort, and potential users of the MRA. From this workshop it was determined what type of product would best suit the land use planners and accurately portray the mineral potential of the province in a usable form. W.J. McMillan was instrumental in the organization of this meeting.

The Vancouver Island regional assessment started in April of 1992 with N.W.D. Massey responsible for compilation of the geology (Massey, 1994). This first assessment developed many of the procedures that were used in subsequent projects. Massey (1995) described the compilation and results of the assessment. The estimation workshop for this region was held in March of 1993 with the final results being supplied to the planning table shortly afterward.

The Kootenays and Cariboo-Chilcotin regions were started in mid 1992. The geology for the Kootenays region was compiled by T. Höy, N. Church, A. Legun, K. Glover, G. Gibson, B. Grant, J. Wheeler and K. Dunn. The results of their compilation were presented in Höy, et al. (1994). The geology of the Cariboo-Chilcotin region was compiled by P. Schiarizza, A. Panteleyev, B. Gaba, and K. Glover. The result of their compilation was presented in Schiarizza, et al. (1994). The estimation workshops for these two regions were run together in March of 1994.

The next three regions were started in April 1993. The Thompson-Okanagan regional geology was compiled by P. Schiarizza and N. Church (Church, 1995 and Schiarizza and Church, 1996). The estimation workshop for Thompson-Okanagan was held on November 8th and 9th, 1994. The Mid-Coast region was compiled by K. Bellefontaine and D. Alldrick (Bellefontaine and Alldrick, 1994) with a description of their findings in Bellefontaine and Alldrick, 1995. The Skeena-Nass region was compiled by D. MacIntyre, C. Ash, and J. Britton (MacIntyre, et al., 1994) and a description of their work is in MacIntyre et al. (1995). The estimation workshops for Mid-Coast and Skeena-Nass regions were held on February 8, 1994.

Compilation of the large Northeast BC region was started in April 1994 by two groups of compilers. The southern portion of the region (south of 56 degrees latitude) was compiled by K. Bellefontaine, A. Legun and N. Massey (Bellefontaine et al., 1995). The northern portion of the region was compiled by D. MacIntyre, A. Legun, K. Bellefontaine and N. Massey (MacIntyre et al., 1995). The estimation workshop for the NEBC region was held in March 1995.

The geology of the NWBC region was compiled by M. Mihalynuk, K. Bellefontaine, D. Brown, J. Logan, J. Nelson, A. Legun and L. Diakow (Mihalynuk et al., 1996). The estimation workshop for the NWBC region was held in March of 1996.

J. Haggart of the Geological Survey of Canada provided the geology of the Queen Charlotte Islands. The compilation was in progress as part of a GSC project and was provided to the Mineral Potential Project through a standing cooperation agreement between the two agencies.

The estimation workshop for the Queen Charlotte Islands was held in March of 1997.

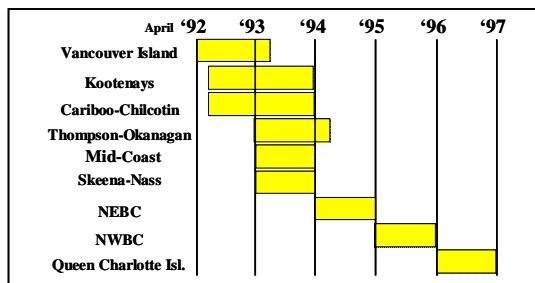

Figure 5. Time chart showing when each of the nine Mineral Assessment Regions was started and completed.

The geological compilation was a major effort involving considerable resources. Originally the resultant information was made available on diskettes in a CAD format (Desjardins, 1994). Eventually, as the World Wide Web matured during the project, this information was made available for downloading in a GIS format or for interactive viewing and integration with other mining and exploration data sets through the [MapPlace](#) website (Kilby, 1999).

During the first part of the project an interim product was developed to provide early input into several of the land use planning processes that were already underway. This interim assessment was known as the Phase 1 assessment (Kilby, 1995). It was preliminary and limited in value because it did not involve undiscovered resource estimations, which were performed for all Phase 2 assessments. The Phase 1 assessment ranked the tracts on the basis of known values, such as discovered resources, past production, past exploration expenditures and number of mineral occurrences. All the tracts were assigned a relative ranking for each of the four values and then these rankings were combined to yield an overall tract ranking. The four rankings were weighted by a factor felt to reflect the relative importance of each value. The weighting factors were 25 for discovered resources, 10 for exploration expenditures and 5 for past production and the number of mineral occurrences in a tract. The result was a quick product whose derivation was easily understood by the users. Several of the data sets used in the Phase 1 assessment were incomplete but the results did give a first approximation of what was expected from the more detailed analysis. Unfortunately, even when the more detailed and

rigorous Phase 2 analysis became available, there was a tendency by planners to prefer and continue to use the Phase 1 product. This preference seemed to be based on the intuitive link between raw information and the final result. The difficulty in gaining acceptance of the superior product was based mainly on the difficulty of explaining the complex simulation process and a reluctance to accept the validity of the expert's estimates. This reluctance tended to be on the part of individuals with mining and exploration familiarity. In retrospect the Phase 1 product was inadequate and its production was discontinued half way through the project.

Acknowledgements

The Mineral Potential Project was completed thanks to the contributions of more than one hundred individuals. Many provided excellent recommendations at the initial planning workshop. Others contributed their expertise to building the required databases and participating in the expert estimation process.

The major component of the project was the geological compilation of the province. British Columbia Geological Survey (BCGS) and Geological Survey of Canada personnel contributed more than 30 professional person years directly to this effort. The individuals and their contributions are too numerous to list here but are described in Chapter 1 of this document. Compilation of the geology for each area was an essential part of this project, the following provided regional leadership for this effort; N.W.D. Massey, T. Höy, P. Schiarizza, B.N. Church, K. Bellefontaine, D. Alldrick, D. MacIntyre, M. Mihalynuk, J. Logan and J. Haggart. Descriptive deposit models specific to British Columbia and essential to the success of this project were generated by many individuals in the BCGS and facilitated by D.V. Lefebvre. E.C. Grunsky contributed significantly to the success of the project through the development of the Digital Deposit Models, GIS and numerical methods expertise. I am especially grateful to P. Desjardins for his invaluable assistance with data preparation and analysis during the project and N.W.D. Massey for being brave enough to shepherd the first region, Vancouver Island, through the assessment process.

A special thanks is extended to the United States Geological Survey staff for their assistance and valuable contribution to this effort. In particular, D.P. Cox, D.A. Brew, D.H. Root and D.A. Singer provided advice and encouragement to the project.

A large number of industry and government individuals participated in the many estimation workshops as expert estimators and as facilitators. Again the number of individuals is too large to list here but their contribution, good humor and patience was key to the success of the project.

The Mineral Potential project received critical funding through the Corporate Resource Inventory Initiative (CRII) funding mechanism of the British Columbia Government.

W.J. McMillan and A. Panteleyev reviewed early versions of this manuscript and suggested improvements. C.E. Kilby of Cal Data Ltd. provided assistance with figure generation. And D.G. MacIntyre provided the final layout and critical review of the manuscript.

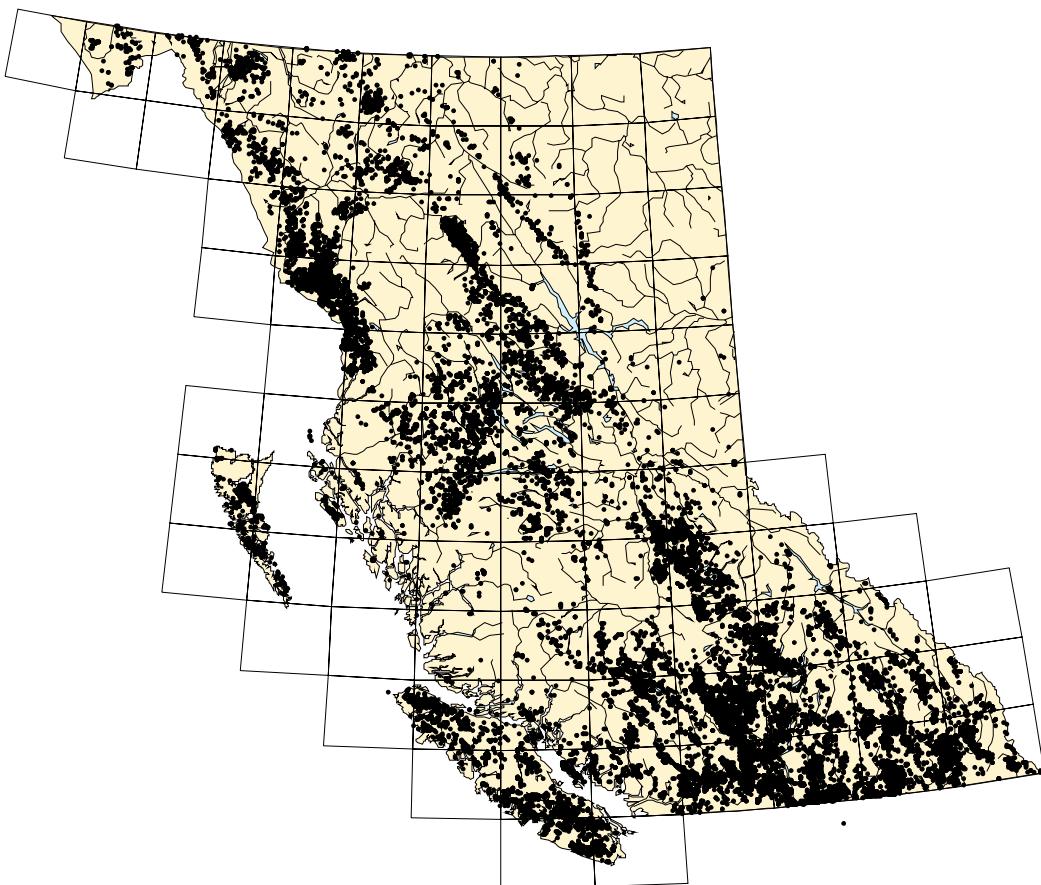

CHAPTER 2**DATA PREPARATION****Existing Information*****MINFILE***

Figure 6. Distribution of mineral occurrences in British Columbia which are described in the MINFILE database.

MINFILE is the British Columbia Ministry of Energy and Mines database of mineral deposits and occurrences. The MINFILE system includes database plus several delivery systems. The information may be accessed free over the Internet, through MINFILE/pc or in hardcopy format. More than 12,000 metallic mineral, industrial mineral and coal, mines, deposits and occurrences are documented in the system (Jones and McPeek, 1992). Information describing each entry includes:

- name, commodity and status (from showing to producing mine)
- location (NTS map, longitude/latitude, UTM, elevation and Mining District)
- mineralogy and alteration
- deposit characteristics, classification and type (based on BC Mineral Deposit Profiles)
- host rock (lithology, stratigraphic names, ages and metamorphism)

- geological setting (tectonic belt, terrane and physiographic area)
- inventory (assays, reserves/resources and production)
- capsule geology description and work history
- references associated with each occurrence.

Figure 6 displays the locations of all the MINFILE information for the province. MINFILE information was used extensively during the estimation workshops. It provided the latest information on each known mineral occurrence in an easily accessible and concise format.

ARIS

ARIS is an acronym for Assessment Report Indexing System, which is a cataloguing and repository system for all the assessment reports filed with the British Columbia government for work performed under the Mineral Tenure Act (Kalinis and Wilcox, 1994). The system contains more than 26 000 reports filed since 1947. The reports provide information on prospecting, geological, geophysical, drilling and other exploration-related activities in the province. The original reports are available in their entirety on microfilm, viewable at provincial government offices. More recently the reports are being digitally captured for access and viewing over the Internet. In addition to the physical report, the system contains metadata on each report including information such as:

- Property Name
- Property Location
- Amount, value and type of exploration work performed.

Figure 7 displays the locations of all the assessment reports available in this system. The assessment reports were used extensively during the geological map compilation process and as a source of deposit reserve and resource information.

Geochemistry

The Regional Geochemical Survey (RGS) is a program to collect stream sediment and water samples, obtain geochemical analyses of these

samples and provide access to these results through use of a provincial database. The program has been operational since 1976. To date results from more than 45000 samples are housed in this system with samples covering about 70% of the province. Each sample is represented by analytical information for up to 40 elements, location information and field observations. This information is available to the public for no charge if downloaded over the Internet or for a nominal charge if delivered as hard copy maps or on digital data storage media.

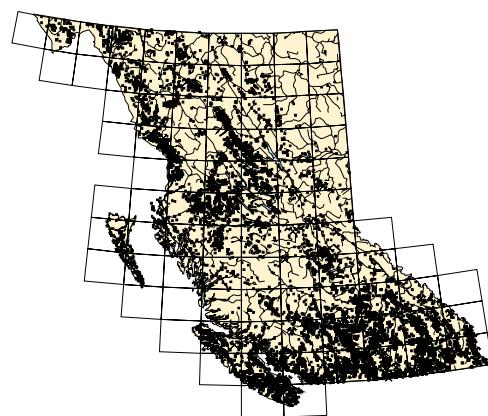

Figure 7. Distribution of mineral exploration assessment reports which are described in the Assessment Report Index System (ARIS) and on file with the BCMEM.

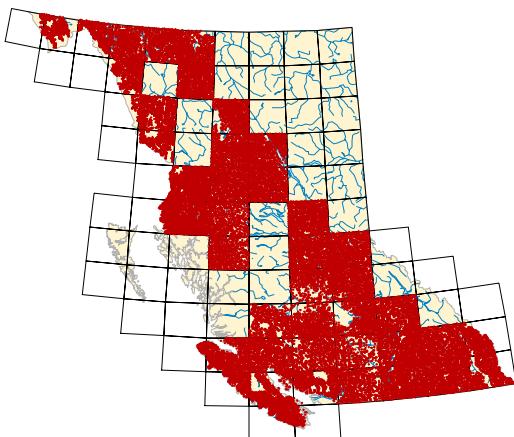

Figure 8. Areas of the province for which information from the regional geochemistry survey was available.

Figure 8 displays the locations of the RGS sample sites for the province. The expert estimators used the RGS data, in the form of hard copy maps, extensively during the estimation workshops. The identification of anomalous pathfinder elements provided important information in the effort to estimate where new undiscovered deposits may be located.

Geophysics

Maps of airborne geophysical survey results for the province were available in published hard copy form. These maps were available in a variety of scales and for a variety of geophysical techniques. The Geological Survey of Canada produced all the maps used during this study. The maps were commonly used during the estimation process to identify areas where hidden deposits may exist and for the definition of geological structures and lithologies.

New Information

Deposit Models

Descriptive deposit models were developed for mineral deposits that were known and believed to exist in British Columbia. This work built on the work by the USGS and others (Cox and Singer, 1986) but modified it to establish models that more closely described characteristics expected in BC. Along with the descriptive models, a classification framework was established in which deposit types were ordered according to their genetic characteristics (Lefebure and Ray, 1995 and Lefebure and Höy, 1996).

Descriptive deposit models are essential to the BC mineral resource assessment process. They provide the standardization required to assure that all participants and users understand exactly what is meant when discussing a given deposit type. The deposit examples given in each model help the estimators visualize the deposit type being estimated. The deposit description assists the estimators during the estimation process by identifying characteristic geological, geochemical, geophysical, alteration and weathering features. Appendix 1 contains an example of one descriptive deposit model. Deposit models can also be viewed by going to <http://www.em.gov.bc.ca/Mining/Geolsury/EconomicGeology/MetallicMinerals/mdp/mdphome.htm>

MINFILE (Mineral Occurrence) Classifications

The MINFILE database of mineral occurrences in the province contains about 12,000 entries. At the start of this project this database was in very good shape but did not contain uniform deposit classification information. As part of this project a series of contracts were let to industry consultants to classify the deposits that were listed in MINFILE. The deposits were ultimately categorized in accordance with the deposit model classification scheme described previously. The contractors assigned a given deposit up to four possible classifications in order of importance. This classification information has now been incorporated into MINFILE and is continually updated as knowledge of the deposits improves. Classification of all known occurrences provided a database that was used for several purposes during the mineral resource assessment. First, the classifications allowed associated resource tonnages to be included in the digital deposit models if they met the qualifying criteria for inclusion in the digital models. Second, knowing the locations of all deposits of a given deposit type in MINFILE was very helpful to estimators during the estimation process.

Geology Compilation

A major effort in the project was to compile the geology of the province at a scale of 1:250 000. Compilation of each region was scheduled for completion so that mineral resource assessments could be made before the planning process focused on that region. Teams of geologists familiar with each region compiled the geology. With the exception of the Queen Charlotte Islands, which was compiled by Geological Survey of Canada personnel, BC Geological Survey Branch geologists, with the occasional assistance of contractors, performed the compilations for the entire province. The regions are large and geological compilations usually required about 10 months of effort. All available information was examined and reinterpreted using the latest geological theories. Typically, all available provincial, federal, academic and industry work was assembled and compiled to form the final product. More than 30 geologist-years were dedicated to this effort. All compilations were produced in digital format and are now available in a common GIS format or interactively viewable over the Internet (<http://www.mapplace.ca/>). As a given

compilation progressed, every effort was made to integrate the geology along boundaries between adjacent compilation regions.

As a result of the compilation there are in excess of 70 000 discrete geology polygons outlined in the province and these have been classified into more than 2200 geological (lithostratigraphic) units. Each of the geological units was given a map code, geological description, a unit name, if appropriate, and a digital code that contained age, lithology and terrane information. Appendix 2 contains a description of the digital coding scheme used to describe the characteristics of each map unit.

This geological compilation formed the basic framework on which all analysis was performed. During the compilation process the compiling geologists became very familiar with the geology of the areas they were working on; this allowed them to define appropriate tracts (see following section) for mineral assessment based on a thorough knowledge of the geology.

Mineral Assessment Tract Selection

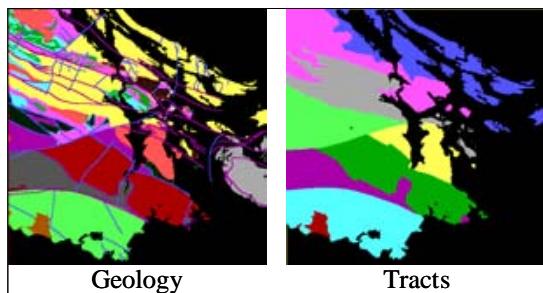

Figure 9. Tracts which were selected for mapsheet 92B and the regional geology compilation on which this selection was based.

Upon completion of the geological compilation, a region is divided into a patchwork of mineral assessment tracts, which are the land units within which mineral resources are assessed. These land subdivisions are based primarily on geological parameters rather than on other land division schemes unrelated to the mineral resource assessment process such as watersheds, forest districts or arbitrary cells based on some coordinate system. Each tract is considered to contain similar geological characteristics for the purposes and 1:250 000 scale of this study. Tract boundaries are geological features such as faults or major contacts. Tract definitions reflect significant differences in lithology, structure and

geological history (Figure 9). Once defined, these tracts become the base unit areas in which the assessments are performed.

There are 794 selected tracts in the province (Figure 10). Tract sizes are dictated by the scale of the assessment, they should be small enough to provide useful resolution to the assessment but not so small as to highlight individual deposits or single rock formations, the average size of tracts in this assessment is about 1000 square kilometres. Occasionally tracts were arbitrarily divided to maintain their ability to resolve differences in mineral potential at the scale of the planning areas. Tracts in this study are significantly different than the permissive tracts of the USGS Three-part methodology (Singer, 1993). Briefly, permissive tracts are defined based on the permissiveness of a single deposit type to exist within the tract boundaries. The tracts of this study are defined on the basis of geology that may or may not control a particular deposit type. All deposit types are evaluated within each of these tracts. Both systems of tract definition have been developed to meet different requirements. The USGS permissive tracts are usually used in studies where a limited number of deposit types are being evaluated. Several often overlapping tracts would describe a single location on the ground, each describing the values for a single deposit type. On the other hand each BC resource assessment tract is evaluated for all deposit types believed to exist in British Columbia.

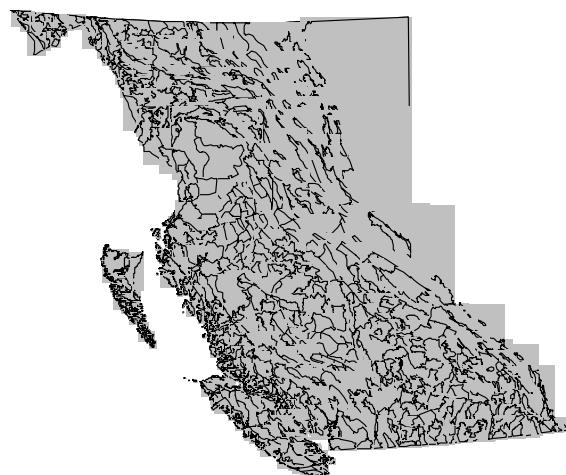

Figure 10. Map of the province showing the distribution of the 794 tracts delineated during the Mineral Potential Project.

Digital Deposit Model Preparation

The two types of input required for the Monte Carlo Mineral Resource Simulator are the experts' estimates of the potential for new discoveries and the digital deposit models describing the grade and tonnage distribution of each deposit type for which the simulator will be used. The digital deposit model contains a list of realistic deposit grades and tonnages for the model types that are expected to be found in the area being assessed. The USGS has constructed many of these models using deposits from around the world. In some cases the BCGS modified the parameters of these models to better describe probable grade and tonnage distributions for deposits likely to be found in British Columbia. In most cases this was accomplished by removing very large deposits from the model. New models were required where an adequate model did not exist. In some cases existing USGS models were combined or subdivided to better accommodate the British Columbia situation (Grunsky, 1995).

Three files are used to describe the digital deposit model for each deposit type to the Mark3B Mineral Resource Simulator (Figure 11). The compiled grade and tonnage data for each deposit (Figure 11a) are easily translated into two ascii text files (Figures 11b and 11c) for input into a preprocessing program which generates a third file describing the relationships between deposit commodities. The data text file, with a .dat suffix, contains a list of deposits that are used to describe the size and grade value

distribution of the deposit type to the simulator. The deposit size in this file is given in tonnes and grades in percentages of the commodities. The definition file, with a .def suffix, describes the contents of both the .dat file and the .bem file. The .def file contains the simulator deposit model identification number, a brief verbal description of the model and codes for the commodities contained in the model (Appendix 3). An example of the commodity code numbers for model 15 (Cu Skarn) are shown Figure 12c. The deposit model identification number is an arbitrary value between 1 and 99 assigned during the simulator setup. The .bem file (Appendix 3) contains matrices of correlations between deposit tonnages and commodity grades. These values

Row 4 indicates there are 3 commodities in this model, Rows 5 through 8 contain the numerical codes for tonnes, copper, gold and silver respectively.

are calculated with the PHASE1.exe preprocessing program described below.

Once the deposits to be included in the digital model have been selected their information is entered into the .dat and associated .def text files (Figures 11b and 11c). Then the PHASE1.exe program is run using these files as input to produce the .bem file that contains all the required information for the MARK3B simulator. The PHASE1.exe program was modified during this project to allow lower grade values to be carried through the calculations. When dealing with low grades, such as gold values in grams per tonne, the original version of the program truncated many of these values when they were converted to percentages. During construction of digital deposit models and their processing great care must be taken to verify that true values are being carried through the calculations. It is important to check the models with the simulator and some test estimate data to make sure the results being generated are appropriate for each model. The .def and .bem files must reside in the same directory as the MARK3B program when the simulator is operated.

Known Resource Tonnage

The final resource assessment value for each tract incorporates both the known and yet to be discovered resources. The known resource values were compiled under a contract as part of this project. Each mineral occurrence in the provincial database was researched to see if any resource values had ever been published. All deposits with resource values were tabulated and their deposit types evaluated. These values were incorporated into the digital deposit models that are used as part of the input to the Mark3B simulator. The results of this resource compilation work were subsequently incorporated into the MINFILE database and have been published as Open File 1995-19 (MINFILE Team, 1995). This publication is the source of resource values used in the final calculation of each tract's assessment score. The resource values were converted to a pseudo-dollar value based on the commodity price list developed for this project.

Commodity Values

A dollar value was established for each commodity to allow the calculation of gross in-place values for each tract. The dollar value used for each commodity was the average market value of that commodity for the ten-year period from 1981 to 1990 normalized to 1986 dollars.

These average values are reported in 1986 Canadian dollars per tonne of commodity. The dollar conversion rates used were based on the Canadian Consumer Price Index. These values were used for both the industrial mineral and metallic mineral calculations to rank the discovered resources in each tract. They were also used to rank the undiscovered estimated resources for the metallic mineral evaluations. A partial listing of commodities and their values is contained in Figure 12 and a complete listing of the file used to value the commodities is contained in Appendix 4.

Industrial Minerals Relative Deposit Value Scores (RDVS)

Metallic and industrial mineral deposit evaluations require different valuing methods. A methodology was developed during the project to provide a meaningful comparison between resource assessment tracts based on their industrial mineral potential. This methodology is described in Kilby *et al.* (1999) and is reiterated below.

Generally metals are sold on the world market, they are relatively highly priced, and transportation costs are relatively minor compared to mining and refining costs. Providing that a company can produce the metal

at or below market price it can generally sell the product relatively easily. Therefore, metal mines can be developed at considerable distances from population centres or processing plants. For industrial minerals the situation is more complex. Many industrial mineral commodities have low unit values. Thus transportation costs are a major consideration and deposits have to be close to market, or have access to inexpensive transportation, to become producers. This situation exists because the geological resources far exceed the anticipated demand for such commodities in the foreseeable future. For example, in some parts of British Columbia there is excellent potential to locate large limestone deposits in areas where it is impossible to transport the rock or possible products (*e.g.* cement, lime) economically to market. In other words, there are significant potential geological resources, but the demand for the commodity limits the value of the resource for the foreseeable future (a relatively uncommon situation for metallic deposits). If the value of in-place resources for deposits like this were used in mineral potential assessments, it would overshadow the value of smaller deposits with readily available markets or high unit values. Since there is a limited market for most of the industrial minerals, estimates of the relative value of industrial mineral resources must often be “capped” to provide a meaningful value for planning processes.

Given the difficulties associated with determining a realistic dollar value for industrial minerals that would be comparable to the dollar value assigned to metallic commodities, the BCGS developed a new approach. In this process two different assessments are made, one for metallic commodities, and one for industrial mineral commodities. The results are presented separately and no attempt is made to equate or combine the results of the two assessments.

The ranking of the land base for metallic deposits is based on the GIPV of commodities in each tract contained in both known and estimated undiscovered deposits. The GIPV of the commodities in each deposit are used to generate a total dollar score per hectare for each tract (Kilby, 1995). These total dollar scores per hectare are then used to rank all of the tracts under consideration. These dollar scores are a ranking tool and do not imply any particular dollar value to the ground being ranked. The GIPV of many industrial mineral deposits is not

an acceptable way to compare their relative values because of market constraints. The industrial mineral assessment used a deposit score system where each deposit type was given a “relative deposit value score” (RDVS) from 1 to 100. The RDVS provides a relative ranking for the industrial mineral deposit types and may vary from one geographic area of the province to another. So while the relative deposit rank of metallic deposits is based solely on the value of contained metals or the “gross in place value” (GIPV) industrial mineral deposit relative rankings consider the following characteristics:

- commodity unit-value,
- size and location of potential market,
- deposit grade and size,
- transportation costs,
- existing infrastructure, and
- extraction costs.

Figure 12 contains a partial listing of the RDVS for some common industrial minerals. A complete listing of the RDVS can be found in Appendix 5. In the industrial mineral resource assessment process, the RDVS is used in the same manner as the total GIPV of all the commodities in a metallic mineral deposit to describe the relative value of each undiscovered deposit type.

CHAPTER 3

RESOURCE ESTIMATION

Orientation Workshop

Mineral resource assessments have been done for many years and there are an associated large number of assessment methodologies. At the beginning of this project a workshop was organized to obtain input from government, university and industry sources on methodology types that would be best suited to our products, databases, resources and time constraints. The orientation workshop was held in Victoria, BC on April 22 and 23, 1992. The content and results of the workshop are described in detail in Kilby, 1992.

The workshop participants decided that:

"The expected products for a mineral potential study are colour maps portraying the mineral potential in several values (metal in ground, in place dollar value, exploration activity, mining activity, tax revenue and employment). Each map package will contain a description of the assessment methodology along with all assumptions. Known mineral resources (producing and non-producing) will be displayed in addition to mineral potential for undiscovered deposits. An economic assessment of the defined mineral potential and known mineral endowment will be included. Products will remain as non-technical as possible to be usable by a diverse clientele. A public release of the data with a seminar on the findings and methodologies of the study is desirable. The term "mineral" is used in the broadest sense and includes solid, liquid and gaseous commodities found in the earth's crust which have value. The resultant database will be maintained in a Geographic Information System and be accessible throughout government in compliance with the Corporate Resource Inventory Initiative"

"The methodology employed to obtain the estimates of the mineral potential will be based on the work of the United States Geological Survey. The method is informally termed the Tongass method, after a study of the mineral potential of the Tongass National Forest in southern Alaska. In this method land tracts of similar geological character are defined and estimates of the mineral potential within each tract are made. Experts from government,

industry, and academia will be involved in evaluating all available data to determine the types and possible number of deposits in each tract. A computer simulator will use this expert input and a database of world tonnage and grade information for each deposit type (corrected for British Columbia) to perform a Monte Carlo simulation and develop probability tonnage and grade curves for each deposit type within a tract. From these curves the expected size, grade and mineral content for each deposit type will be determined. When all deposit types within the tract have been analyzed the total will be reported in map form and/or translated into some other values such as dollars, taxes, jobs, etc. At various points in this process experts will be involved by inputting required parameters and auditing output. It provides probability parameters for each estimate and incorporates the expertise of a varied knowledge group."

In summary the basic conclusions of the workshop were that the process must:

- be quantitative rather than qualitative
- provide a ranking of the land base
- involve experts from mining and exploration industry
- produce digital GIS compatible products
- make all information readily available.

In the end, the project produced:

- only metallic and industrial mineral evaluations; coal, aggregate, petroleum and natural gas were not evaluated by this program.
- in-place dollar values to rank the metallic mineral assessment and a new parameter Relative Deposit Value Score (RDVS) to rank industrial mineral assessments.
- products that were maintained in a Geographic Information System (GIS) as well as provided to clients over the Internet.

In the end, the project:

- modified the USGS three-part methodology (Singer, 1993 and Brew, et al., 1992) for use in this project. Several significant changes

were made but the basic assumptions were similar to those made by the USGS for the Tongass study.

- held estimation workshops for each study area that employed industry consultants and government staff to make the probabilistic estimates of expected numbers of undiscovered deposits.
- geologists and land use planners examined and applied results from each study area, thus providing a very good review of the methodology used and conclusions reached.

The estimation procedure that was developed incorporates several significant modifications to the USGS three part methodology. In the USGS methodology a single set of estimation values is sent to the simulator. If a group of estimators were involved, this single estimation would have been obtained by consensus. A great deal of work in the field of psychometrics has shown that a true consensus may be unachievable, and certainly would not be achievable within the time constraints we faced. The interaction of people's personalities and agendas would override the information being solicited in a group setting (Acquired Intelligence Inc., 1993). We wanted to reduce stress on the estimators to capture their true feelings rather than the feelings they were ready to defend. For this reason we allowed each estimator to make their own estimates in confidence. We then used the weighting scores provided by the estimators to produce a weighted average of the estimates and obtain a single group estimate for input to the simulator.

The Mark3B simulator requires estimation input at discrete confidence intervals. However, making estimates at specific confidence intervals is believed to restrict the accurate expression of the estimators' true feelings. This is believed to be due to the fact that a great deal of concentration is diverted to thinking about the confidence intervals rather than the estimate being made. An alternative way to record the estimates, and the one we used, is based on fuzzy logic theory. In this method the estimator records the value as a position between two end points. The two end points being, "no chance of a deposit" (0% confidence) and "certainty of a deposit" (100% confidence) (Acquired Intelligence Inc., 1993). The simple linear scale is believed to capture a more realistic sample of the estimator's feelings than the discrete

probability level entry style of the USGS three part methodology. Once the estimates are recorded in this manner discrete probability level values are derived numerically.

Estimation Workshops

An estimation workshop was held for each region to solicit the required expert estimations for the assessment. Industry and government personnel familiar with a given region and mineral deposit types being assessed were invited to the workshop. These experts were divided into groups of 3 to 4 individuals and each group was assigned a series of deposit types to assess. A large amount of background information, such as the geological compilation, MINFILE occurrence maps and geochemical maps were prepared prior to the workshop to assist the estimators.

Estimators

Estimators were invited to the workshops based on their expertise in the area being assessed and their familiarity with specific deposit types. Their availability also played a role, both in the scheduling of workshops and in the selection of participants. Some estimators volunteered their time while others were given contracts for their time at the workshop. Workshop attendance costs for estimators from government and some companies were covered by their employers. It was realized from the outset that the quality of estimators would vary, not only in their general qualifications but also their familiarity with the area being assessed and the mineral deposit types they were estimating. The mineral discovery process is a very nebulous process and no attempt to rank the estimators capabilities as explorationists was made prior to the workshop. However, during the estimation process itself the estimators provided this control through a scheme of confidential rankings of their fellow estimators.

Workshop Data

Geological information formed the foundation of all discussions during the workshops. At the workshops, this basic information was provided as paper maps of the 1:250 000 geological compilations that were completed as part of this project. Other spatial data sets such as geochemistry, mineral occurrences and tract outlines were usually superimposed on the geology in the form of overlays or plotted

directly on the printed maps. In general, as much as possible of the spatial information was made available in the same projection and at the same scale to facilitate efficient use of time by the estimators.

For some data sets it proved to be more important to have the supporting information available in its original format rather than in a totally integrated format because that was how the estimators were familiar with it. Geophysical information, for example, was always made available but was usually in its published format. Though the format was not digital, it was extensively used for some deposit types and proved to be easily integrated by the estimators.

In addition to the information presented in map format, a large amount of material was in text format. A compendium of the following information was provided to each estimation table:

- descriptive deposit models
- graphs of the digital deposit models
- a list of all deposit types with their median tonnages and grades
- a small map displaying all tracts in the study area
- a list of all tracts and their areas
- a list of all resource bearing deposits by tract
- a list of all MINFILE occurrences by tract with deposit type information
- a tracking sheet for the table facilitator to log estimates made.

The MINFILE/pc database system was also available at all workshops.

In addition to information made available at the workshops, estimators often brought company information, usually in the form of private reports or works-in-progress that proved extremely useful. This private information was freely shared at the estimation tables and was essential to the success of the process. More important still was the personal experience and knowledge of the estimators; it was key to the success of the assessments.

Estimation Process

Each estimation workshop began with a presentation that described the estimation process, its rules, the information available, the estimator's responsibilities and how the estimation results would be processed. A second presentation by a geologist involved in the area's geological compilation and tract selection described the geology and metallogeny.

Figure 13. An estimation table with estimators and facilitator. Note other estimation tables in the background.

The invited estimators were divided into groups of 3 to 4. Each group was assigned a series of mineral deposit types and their task was to provide estimates for each tract in the entire study area. For example, they might be asked to estimate the number of copper and iron skarns and multi-element vein deposits for the whole of Vancouver Island. Each group or table consisted of these estimators and one facilitator. The facilitator's purpose was to keep the process on track, manage the coding sheets and make sure the rules of estimation were followed. The facilitator did not make any estimates but was free to participate in any discussions or assist in any way possible. Each group was assigned a table to work at and all tables were relatively close to each other to promote consultation with other tables should the need arise (Figure 13).

Four basic guidelines were followed by the estimators:

- 1) The estimators made their own estimate in confidence. No table consensus was sought.
- 2) Each person made a confidential evaluation of the other estimators with respect to each tract/deposit model combination.
- 3) If all estimators agreed that a particular deposit type would not be found in a

tract, then no estimate was made, but if at least one estimator felt there was a chance for the deposit type to occur in the tract then everyone made an estimate.

- 4) The deposit size, for this process, was the median tonnage of the digital deposit model for the deposit type.

		=50																	
<div style="text-align: center;"> Tract Confidence </div>																			
Notes:																			

Figure 14. Estimation coding sheet as it would appear following the completion of one estimation.

A typical sequence of actions for the estimate of a single tract/deposit type combination would be:

- 1) A general table discussion of the tract geology and the characteristics of the deposit type would often result in the group identifying characteristics of the tract that were favourable for the deposit type. All available information sources would be used during this step, such as MINFILE, geochemistry, geology, geophysics and personal knowledge.
- 2) The group would identify any known occurrences of the deposit type being estimated from MINFILE. Care was taken to properly include these known occurrences. So long as an occurrence did not have defined resources, it was included in the estimates of

undiscovered deposits. If it had significant known resources but was not expected to be enlarged through additional exploration by at least the amount of the digital deposit model median tonnage, it was excluded because the resources would be counted as inventory. If it was felt that there was an opportunity for the deposit to be increased in size by at least the amount of the median tonnage, an estimate for this additional amount could be considered in estimators' evaluation. In this case, the already known resources would be considered as inventory and the potential for new resources possible through additional exploration would be considered as potential resources.

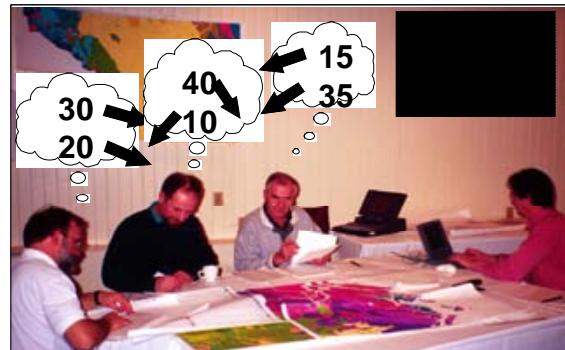

- 3) When each estimator recorded estimates for a single deposit type they would do the following:

- Ask themselves "How confident am I that at least one more deposit of the median tonnage size can be found in this tract?" They would then place a tick mark on the estimation scale and the number one above it to record the number of deposits associated with the estimation tick mark (Figure 14).
- Then they would proceed by asking themselves how confident they were that at least two deposits of the median tonnage could be found. In this instance the probability estimate tick mark is labeled 2. Estimators were not restricted to increments of one deposit but could choose any number that was appropriate. They were, however, limited to a total of six, tick marks on the scale.
- Then, if they wished they could add a single tick mark to the scale, which recorded the confidence level, at which they were confident no deposits could be found. This option was often confusing and required care in use. If this option was not provided, then the simulator assumed a default value for zero deposits because the

program always assumes that there is some chance of the deposit type existing. Although this feature is used to help constrain the simulator, it was seldom used by the estimators.

- Following completion of their estimates, they were required to evaluate each of the other estimators for that tract/deposit type combination. To do this they recorded the estimators' initials and record a ranking score. They were required to distribute 50 ranking points between the other estimators at the table. In this way they could adjust the weight placed on the others' estimates in accordance to their feeling of each person's knowledge of the tract and deposit type (Figure 15). The calculations involved in using these values to produce a weighted average of the actual estimations will be discussed in a latter section on data processing.
 - Finally the estimators would place one tick on the estimation confidence scale recording their overall feeling of the quality of that estimate. This was not a measure of their confidence in their own estimation but was a measure of their confidence in the quality of the estimation made by the group as a whole that included the general group knowledge of the tract and deposit type, the quality of the information available and the quality of the estimators. This value is not used in calculating the potential of the tracts but has value for gauging the quality of the estimate should the issue arise in the future.
- 4) Once all the estimates for the tract/deposit type combination were completed, the facilitator would check to make sure all required information had been recorded and then staple all the work sheets together.

- 5) The table would then move on to the

next tract/deposit type combination.

Figure 15. Illustration of how estimators might distribute their 50 points based on their feeling of the other estimator's knowledge of a particular deposit type in a tract estimate.

CHAPTER 4

ESTIMATE EVALUATION

Introduction

Upon completion of the estimation of the potential for undiscovered mineral deposits in a tract, the information captured on the coding sheets was converted into digital files. These files were then processed to provide input into either the Mark3B simulator or the industrial mineral evaluation process.

The discussion in chapter 2 under the heading Industrial Mineral Relative Deposit Value Scores describes the reasons for treating metallic and industrial mineral deposit estimates and calculations separately and in a slightly different manner. Despite this, the procedures for producing these two different styles of assessments are parallel in most respects. The major difference is that the Mark3B Mineral Resource Assessment Simulator is not used for the Industrial Mineral process. Figure 4 illustrates the assessment process for both types of commodities showing the stages from information gathering through to the estimators making the final ranking of the tracts within a region.

Pre-Simulation Estimate Preparation

Coding Sheet Digitization

Following a workshop the estimation coding sheets were processed. The initial step was to digitize the linear Estimate Scale on each sheet. This digitization involves measurement of the distance along the estimation bar, from 0 to 100 for each tick mark made by the estimator.

In practice, a scale was constructed which matched the length of the estimation bar and was graduated in 5% increments. This scale was used to measure the probability value of each tick mark along the estimation scale (Figure 16). The

Figure 16. Example of a digitized coding form.

same measurement procedure was used for the one tick mark made on the Tract Confidence bar.

Data Entry

Once all the estimation coding forms were digitized, the information was recorded to computer files. To simplify this process and provide some rudimentary error checking a Visual Basic program, MINCODE.exe, was written. The program provides drop down menus for all valid estimator initials, deposit codes and tract identifications to reduce data entry errors. In addition it checks to make sure that the estimator weights and initials are valid. It also verifies the order of the deposit number/probability entries. Figure 17 shows this data entry form. The sliding scale bars also provide a useful visual check during the data entry.

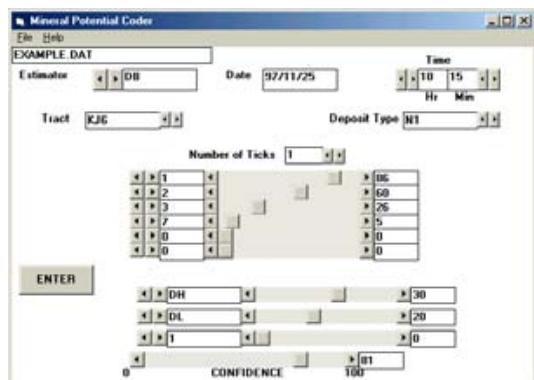

Figure 17. Screen display of the Mineral Deposit Coder program MINCODE.exe. The VisualBasic program reads ASCII input files containing the number of estimators and their initials (Figure 18a), deposit models and their corresponding MARK3B simulator number (Figure 18b) and tracts in the assessment area (Figure 18c) to provide the operator with valid selections for the Estimator, Tract and Deposit Type entry fields. The program also does error checking and will not accept the input until all obvious errors are corrected.

Typically data entry was performed on coding sheets from one table (one group of estimators) at a time and proceeded either by tract or by deposit type. In this way the entry form retained much of the entry information from the previous sheet and significantly reduced the amount of typing and potential data entry errors. The MINCODE.exe program reads three small text files for each group that contains the valid estimator initials, tract names and deposit types. It then presents these to the entry personnel during the entry process. If the program encounters an error, it prompts for a correction, no information is accepted until all the form error checking is satisfied. As each sheet is coded and accepted by the form program a single line is added to an output file.

Estimation Weighting Calculation

Upon completion of the data-entry phase the multiple estimates for each group/tract/deposit combination were reduced to a single weighted estimate based on the weights assigned by each estimator at the table. The QuickBasic program RAW2MARK.exe (Appendix 6.) read the output file from the data entry program and produced a single weighted estimate for each tract/deposit type. Two output files were created

Figure 19. Files and commands associated with running the RAW2MARK program. a) Example of the commands required to run the program. b) example of the input to the RAW2MARK program which is the output from the coding program. c) example of the summary output from the program and d) example of the command output from the program which forms the input to the MARK3B simulator program.

discrete confidence intervals of .90, .50, .10, .05, .01. The program uses linear interpolation between the values noted on the coding sheet to calculate the number of deposits expected at the five discrete confidence points needed for input to the Mark3B simulator. Simple weighted averaging is used to combine all estimates for a single tract/deposit type combination.

As described previously, each estimator was required to rate each of the other estimators at the table by distributing 50 ranking points between the other estimators based on the estimator's feeling of their relative knowledge of the deposit type and tract being estimated. Each estimator was also assigned 50 ranking points to assure that each estimator's estimations provided at least some input to the group estimate as the estimators could not apply any ranking points to their own estimations. Thus the total number of points for any estimate would be 100 times the number of estimators. The weighting of each estimator's values in the combined result would then be their total number of points divided by the total number of points for the whole table.

The input file for each run of the RAW2MARK program must contain groupings of equal number of estimators. A separate run of the program is required for estimates from tables where there were groupings of different numbers of estimators.

Figure 19 illustrates this process for 2 tracts that were estimated by 3 estimators for the copper porphyry deposit type (O2). The weighted average estimate values for these two tracts are shown in figure 19c. This file contains the tract name, deposit type code, and the number of deposits estimated to exist at each of the 5 confidence levels. These 5 averaged estimation values form the basic input to the Mark3B simulator. Figure 19d illustrates the command file generated by the RAW2MARK program which is used as input to the simulator.

Industrial Mineral Resource Calculation

As described earlier, the industrial mineral (IM) resource assessment calculations differ from those performed for metallic minerals. It is after the weighting stage (Figure 4) that the processing of the estimate information for the two types of commodities diverge. Once the weighted mean

Figure 20. MSAccess table containing the basic information for the Queen Charlotte Island industrial mineral assessment. Information includes the tract name, area of tract in square metres, dollar value of the known resources and total RDVS for each tract at the 90%, 50%, 10%, 5% and 1% confidence level.

estimates for each IM deposit type, in each tract, have been calculated the deposits are valued by multiplying the number of deposits by the RDVS (see chapter 2). A QuickBasic program SCOREADD.exe performs this operation. The output file contains a sum of the deposit scores for all the deposits in each tract and displays these sums for each of the 5 confidence intervals.

At this point the estimate portion of the industrial mineral assessment can be integrated with tract area and inventory information to expedite final tract ranking calculations. This integration and calculation step is performed by the program MSAccess. For example, Figure 20 contains a table listing of the initial tract information for each of the nineteen tracts in the Queen Charlotte region. Two MSAccess queries are used to perform some simple calculations on this data, add some additional fields and perform the ranking of the tracts.

The calculations performed by MSAccess are identical for industrial minerals and metallic minerals and are described in the Post-Simulation

Calculation section. The only difference is that the values in the estimation fields for metallic commodities are in pseudo-dollars and the corresponding values for industrial minerals are RDVS.

Metallic Mineral Resource Calculation

Mark3B Mineral Resource Assessment Monte Carlo Simulator

The original Mark3 simulator was developed by the USGS and has been used in many mineral resource assessment projects (Brew *et al.*, 1991, Cox *et al.*, 1986, Cox, 1993, Root *et al.*, 1992 and Spanski, 1992). An excellent example of one of these projects, and a description of the operation of the simulator, can be found in Root *et al.*, 1992. The simulator itself was released in 1998 (Root *et al.*, 1998). Originally the simulator was available in the Fortran computer language and required significant computer resources to operate. During this project the Mark3 simulator

was rewritten in QuickBasic by the USGS so that it could operate on the common PC platforms. This new simulator was called Mark3B to designate its QuickBASIC source code. This QuickBASIC version was provided to our project along with considerable advice and recommendations (Root, Pers Commun 1993). The Mark3B was modified slightly to provide a custom output file that simplified the data processing involved in this project. The functions of the simulator have been described elsewhere (Brew, 1991 and Root *et al.*, 1992) but the eleven basic steps that the simulator goes through during a calculation are summarized here (from Root, unpublished).

- 1) Choose, at random, the number of deposits for this iteration. If it is zero, go to step 10 otherwise go to step 2.
- 2) Choose, at random, a suite of metals. Go to step 3.
- 3) Evaluate, at random, $m+1$ independent standard normal random variables (m = the number of metals in the model). Go to step 4.
- 4) Calculate the linear combinations of the values of the standard normal random variables from the matrix of coefficients in the "bem" file to obtain the values of $m+1$ dependent standard normal random variables. Go to step 5.
- 5) Find dependent uniform values from the dependent standard normal random variables (by the inverse of the cumulative standard normal distribution function evaluated at the values determined in step 4). Go to step 6.
- 6) Find tonnage and grade values from the dependent uniform values and the inverse of their cumulative distributions. Go to step 7.
- 7) Add the amount of each metal to its total for the deposits in this iteration. Go to step 8.
- 8) Check to see whether there is another deposit to do in this iteration. If there is, go to step 2, otherwise go to step 9.
- 9) Check to see whether 4999 iterations have been completed. If not, go to step 1, otherwise go to step 10.

- 10) For each metal, sort the 4999 totals from each iteration (least being rank1 and greatest being 4999).
- 11) Graph 1 minus the rank divided by 4999 on the y-axis versus the quantity of metal on the x-axis to obtain the assessed distribution of the metal in the area.

In addition to the above steps, a modification to the program extracted the total amount of each commodity calculated for each tract at five probability ranks (0.9, 0.5, 0.1, 0.05, 0.01) and output this information to a file called SIMTOT.all.

The simulator can be operated in either interactive or batch mode. With the output from the RAW2MARK.exe program the batch mode of operation is very straightforward. Figure 21 contains the command to start the simulator and the output file required for further calculations. Several output files are constructed by the simulator and are available for printing and viewing but are not discussed here.

The results in the simulator output, SIMTOT.all, are the tract number, the deposit type number, the commodity, a mean tonnage value, and the volume of the commodity in tonnes expected to be discovered at the five confidence levels (.9, .5, .1, .05, .01). The next step in the processing of the metallic mineral estimates is to convert the commodity amounts to dollar values to allow integration of all the commodities into one value for the deposit and subsequently the tract. The program SIM-VALU.exe performs this function by multiplying the commodity tonnage by a dollar value for each commodity. Similar to the SCORE_ADD.exe program used for industrial mineral deposits, this program also adds up the commodity values from all deposit types in each tract to give a tract total value. Prior to running the SIM-VALU.exe program, the input file, SIMTOT.all, must be sorted by tract and commodity. This can be achieved easily in any spreadsheet program. Figure 22 contains examples of the input and output files along with the commands required to run the program.

At this point the estimate portion of the metallic mineral assessment is ready to be integrated with tract area and inventory information to facilitate final tract-ranking calculations. This integration and calculation step is performed in MSAccess. Figure 23 contains a table listing of the initial

tract information for each of the nineteen tracts in the Queen Charlotte region. MSAccess is used

to perform the calculations to determine the final tract ranking.

It is written to a file called SIMTOT.ALL.

Post-Simulation Calculations

Final ranking of tracts for both the metallic and industrial minerals assessment are performed in exactly the same way once the valued estimation information has been merged with the resource inventory and tract area information. MSAccess carries out the manipulations required to produce the final rankings. The calculations are all based per hectare. In the calculations, each tract is ranked using each of the six confidence interval values individually, and then the six rankings are weighted by their probability and combined to produce the final rank value. This is done to isolate the estimates at the various confidence levels so they do not bias the final ranking score. This approach prevents an extremely high ranking at a low confidence level from overshadowing a lower ranking at a high confidence level (Figure 24).

For each of the variables (confidence interval levels), the tract is assigned a rank based on that variable normalized for the size of the tract (area). The rank numbers run from one, for the lowest ranking, to the total number of tracts for the highest ranked tract for that variable. The rank numbers for each variable are then weighted by their confidence value and summed to give a total score for each tract. For the final ranking, the scores for each of the tract are sorted from lowest to highest and assigned ordinal numbers from 1 to the total number of tracts to give the final ranking.

The weightings assigned to the variables are, 1.0 for the inventory values, 0.9 for the 90% confidence values, 0.5 for the 50% confidence values, 0.1 for the 10% confidence values and 0.01 for the 1% confidence values. Figure 25 contains the metallic and industrial minerals ranking tables for the Queen Charlotte Islands assessment region.

CHAPTER 5

RESULTS AND PRODUCTS

Provincial Resource Assessment Map Products

Two maps were generated to display the relative ranking of the mineral potential across the province. One map illustrated the mineral potential ranking based on metallic mineral commodities (Figure 26) and the second map illustrated the mineral potential based on industrial mineral commodities (Figure 27). These maps are useful to illustrate very broad trends in the potential but are not valid for detailed analysis of tract rankings. The maps do not include any measure of important variables that have affected resource discovery and development in the province, such as exploration exposure and developed infrastructure. The mineral assessment evaluation was carried out on a regional basis. Comparison of tract rankings from widely separated regions may result in flawed analysis due to their very different geographical and social context. Two tracts may have exactly the same mineral potential but due to the remote location of one relative to the other it will not have received the exploration attention over time and will likely have a lower mineral potential ranking than the tract that received more exploration. Detailed comparison of tract rankings within a region or closely separated tracts in two adjacent regions are valid, as they will in most cases have shared a common exploration and developmental history.

Regional Resource Assessment Map Products

Two regional maps and accompanying attribute information were generated for each of the nine Mineral Assessment Regions (Figure 3) as the studies were completed. One map was used to illustrate metallic mineral potential and the other used to illustrate industrial mineral potential. These products were delivered to the appropriate land use planning group in digital format for integration into their digital database of stakeholder values. When delivered, the tracts within the region were grouped into 10 classes based on their ranking values. Each of the ten classes represented approximately one tenth of

the region's land area. No attempt was made to assign a discrete label such as High Mineral Potential to any portion of the classes. What was provided was a product that could be used to assess the relative importance of a tract in a region with respect to its mineral potential. Unfortunately, the number of classes was often reduced to 3 by the land use planning group participants. The three-fold breakout inevitably led to the High, Medium and Low ranking labels being applied to some derivative maps. This was a poor practice as it implied to users unfamiliar with the process that some tracts had 'Low mineral potential' where in fact they simply had lower mineral potential than other tracts in that particular region. As the product was designed to meet the planning groups mandate of alienating a given percent of the region's area from development, the relative ranking product was ideal. Unfortunately, the products were being used for other agendas where there was a desire to identify areas of Low (little or no) Mineral Potential. Under this scenario tracts which ranked low in a particular region with relatively high mineral potential compared to other regions became identified as having unimportant mineral potential where in fact they may have very important mineral potential when viewed in a provincial context. For this reason it is essential that individuals knowledgeable of the estimation process ensure these products are used appropriately.

Tract Products

A number of attributes were compiled and generated for each mineral assessment tract. Much of this information is available in various display formats through the BCGSB's MapPlace Internet Map Server service (www.mapplace.ca). Compiled tract attribute information includes values such as: tract area, number of MINFILE occurrences, value of known resources, value of past production and value of exploration expenditures (from ARIS). Mineral Resource Assessment generated-data for each tract includes: the number of potential new deposit discoveries by type, dollar value of commodities in potential discoveries, types of commodities expected to be discovered and ranking of tract

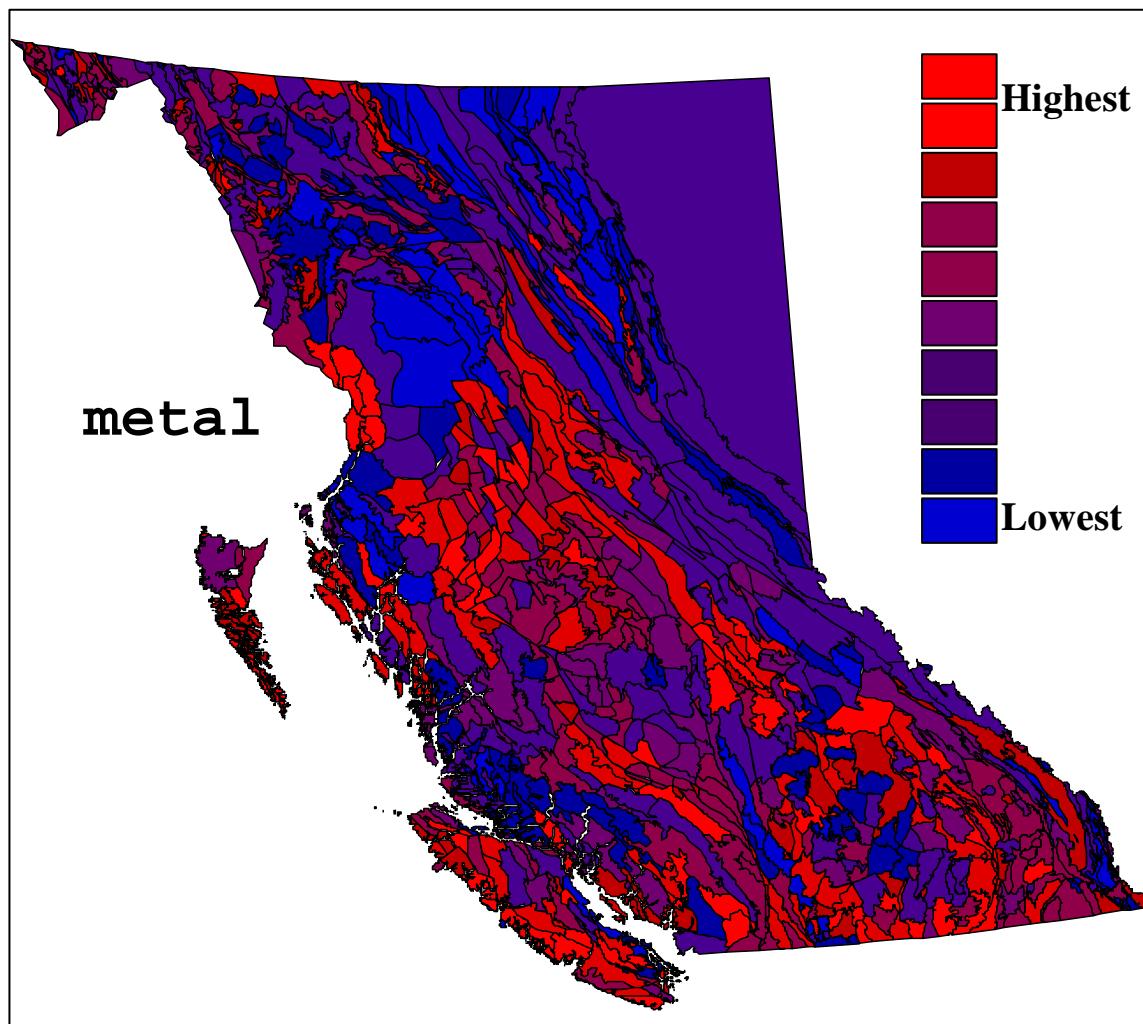

Figure 26. Maps illustrating relative ranking of metallic mineral assessment tracts for the province. Each of the 10 classes contains about 10% of the land area of the province. Comparisons between tracts is only valid for tracts in close proximity to each other. Comparison of tracts significant distances apart based on this methodology is not valid.

relative to the other 794 tracts in the province. Appendix 7 contains tabulations of this information and graphical displays of the locations of each of the 794 tracts included in the analysis program.

Deposit-Type Products

The products generated for the land use planning process were the result of combining the values of all commodities contained within all deposit types to arrive at a tract total value. A valuable preliminary product of the whole analysis

process is the expert estimation of the number of expected new discoveries of each deposit type in each tract. These maps display the discovery favourability for a single deposit type across the province. They are therefore excellent first approximations of prospective areas in which to explore for particular deposit types. These maps may be accessed over the Internet at the MapPlace (www.mapplace.ca) and are reproduced in Appendix 8.

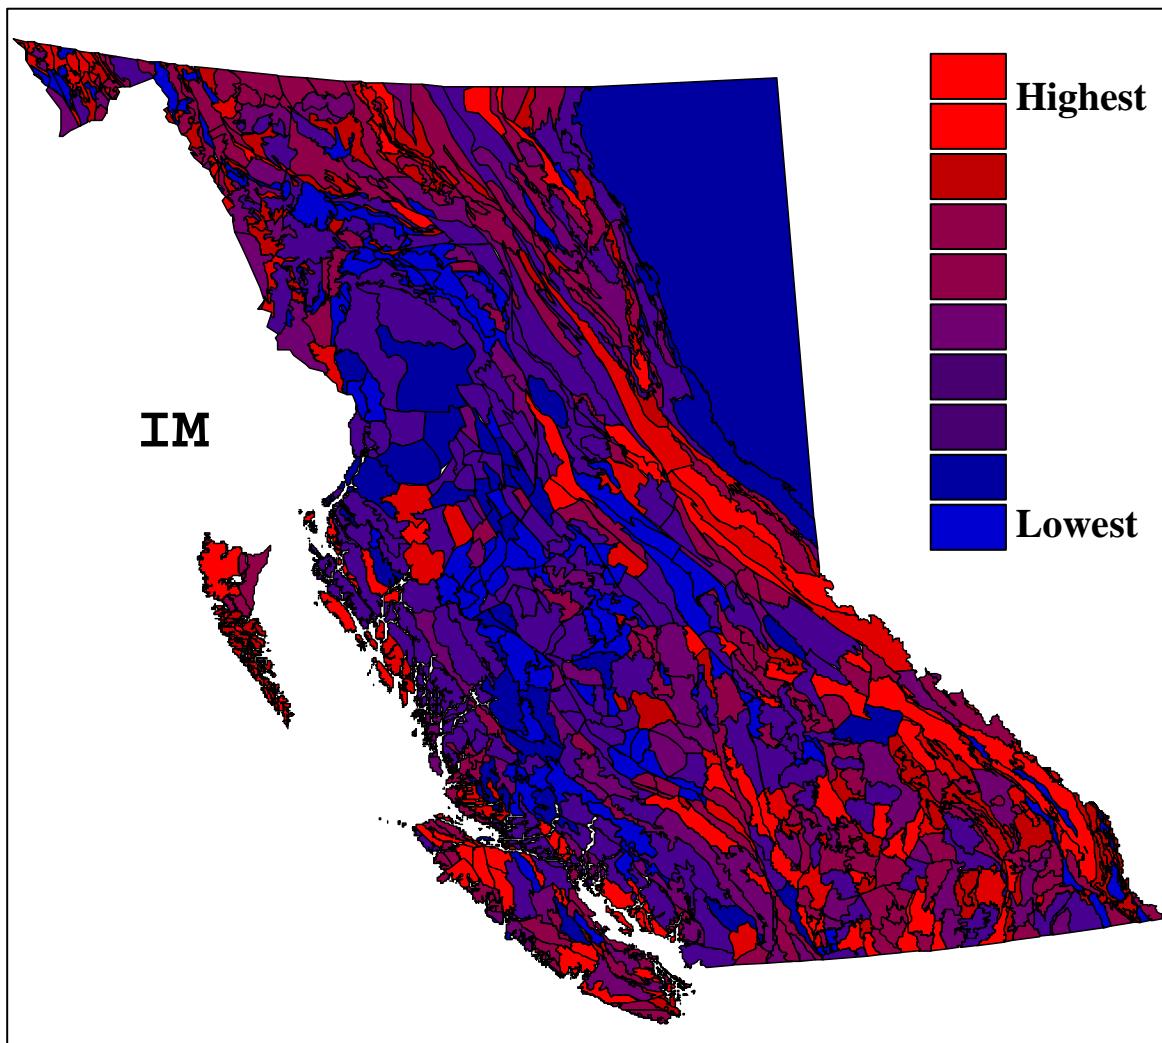

Figure 27. Maps illustrating relative ranking of industrial mineral (IM) assessment tracts for the province. Each of the 10 classes contains about 10% of the land area of the province. Comparisons between tracts is only valid for tracts in close proximity to each other. Comparison of tracts significant distances apart based on this methodology is not valid.

CHAPTER 6

UTILIZATION OF MINERAL RESOURCE ASSESSMENTS

Limitations of Mineral Resource Assessments

Mineral Resource Assessment maps and products are a very valuable component in any land use planning process. In jurisdictions containing substantial mineral resources, such as British Columbia, they are essential. Although considered essential to the process, they are only a component of the information needed to make an informed land use decision. There are a number of limitations to any Mineral Resource Assessment product.

Time Related Issues

The principle limitation is the timeliness of the assessment. All assessments are made based on historic information and current knowledge. They are therefore, a snapshot in time. They cannot be expected to accurately portray the mineral potential of land far into the future. Our knowledge of mineral deposits will advance with time which will change our ability to discover and develop deposits in unimagined environments, at greater depths and with lower grades. New technologies will allow certain deposit types to be discovered with greater ease and will allow the profitable exploitation of deposits that are currently uneconomic. In addition deposit types that were not believed to exist in the province during the analysis may subsequently be discovered. Societal demands for certain commodities will change causing the relative values of deposits to change and thus the relative ranking of mineral assessment tracts.

Although the current MRA will not be valid indefinitely into the future, it has been designed for routine updating. Only the components that have changed since the last evaluation need to be adjusted to calculate a new assessment. If there is a fundamental change in the relative values of the various commodities in the assessment these changes can easily be made and the relative tract rankings recalculated. If a new deposit type is considered valid it can be added to the mix. It will be estimated in exactly the same manner as deposit types in the initial study and its values simply added to those of the other deposits and

then the tract ranking may be recalculated. Also the acceptable grades and tonnages of a given deposit type may change over time with new discoveries or changes in model classifications. In these cases the involved deposit types must be re-estimated for the whole province and the resultant values used to replace those for the equivalent deposit types in the initial study. In this way the MRA may be maintained indefinitely through incremental updates where required.

Scale Related Issues

This MRA was conducted at a scale of 1:250 000. This scale was dictated by the client of the information and was used to present all resource evaluation information from all sectors to the various planning processes. The scale of analysis dictates the required resolution of the analysis units (tracts). Tract size limits the size of planning areas in which the tract can provide any information of value in differentiating the planning area. For example, if a planning area contains a single mineral assessment tract the mineral assessment information adds nothing to the planners' abilities to subdivide the planning area on the basis of mineral potential. In British Columbia as the planning process progressed, smaller and smaller study areas were proposed and land use planning initiated. In some LRMP areas only a few 1:250 000 scale mineral assessment tracts covered the whole LRMP. In these small areas an analysis of greater detail than the initial 1:250 000 study was required to be able to make any reasonable contribution with respect to mineral potential. In some studies, new more detailed assessments, were made based on different schemes of ranking the area with respect to mineral resources. Some of these new evaluations did not utilize a rigorous estimation of mineral resources but rather based the product on known parameters such as existing discoveries, mineral tenure and geochemical anomalies. In many cases the objective of the assessment information was different in the different scales of planning. In the provincial scale planning exercise the objective was to alienate ground on the basis of a given area percentage. In the more detailed planning

exercises often the information was used to defend existing areas of known mineral endowment from alienation.

In some cases the information in the 1:250 000 scale MRA can be used to generate a more detailed product without conducting a new estimation of undiscovered resources. Usually the mineral assessment tracts contain a variety of geological units. The units, though grouped at a scale of 1:250 000, may in fact be permissive for different types of mineral deposits. If deposit types contributing significantly to the total value of a tract prove to be controlled by geological or topographical features that can be delineated within the tract then the associated values of known and estimated resources can be placed in these sub-tracts. By this means it may be possible to extract greater spatial resolution from the original study without performing a new assessment but simply redistributing the previously calculated values. All of these approaches have their own strengths and weaknesses but their requirement is an obvious illustration of the limitation of any study due to its spatial scale.

Evaluation of Assessment

The fact that the assessment is based on expert probabilistic estimations rather than direct measurements limited the acceptance of the results in some sectors. Many participants in the planning process were not familiar or comfortable with the concept of expert estimation. They were familiar with resources that to some extent could be directly measured or at least had the appearance of being directly measurable. In most cases the basic component of mineral potential, the mineralized material, cannot be seen. A comparison of the assessment's estimated discoverable mineral resources with known resource values can help alleviate apprehension on the part of users.

Assessing the results of the Mineral Resource Assessment is a complicated problem. It is not possible to compare the estimated future discoveries to future discoveries as the future is not yet here and will never be. We could qualitatively assess the results by comparing the number of predicted future discoveries to historic discovery patterns and quantities. This will give a feeling of the assessments general validity but

will in no way be a test of its accuracy. Other potential measures such as its acceptance in the land use planning process and by industry specialists are only testing its acceptance, a human perception that varies with the individual and their agenda, which does not necessarily correspond to reality.

Comparison of estimated future discoverable resources with discovered resources on a provincial scale provides a feeling for the "reasonableness" of the expert probabilistic estimation process (Figure 28). Historic resource values such as past production and discovered resources document the amount of metallic mineral resources discovered to date. The value of past metallic mineral production in British Columbia is about \$45.5 billion (1986). The value of documented discovered metallic resources is about \$170 billion (1986). In comparison, the value of estimated new discoveries is \$23.5 billion and \$660 billion (1986) for estimates at the 90% and 50% confidence level. The 50% confidence value predicts that about $\frac{3}{4}$ of the provincial mineral endowment remains to be discovered. Again, the actual mineral endowment of the province will never be known but comparison of the estimated remaining resources to the discovered resources provides a level of comfort in the estimates in that they are in the same order of magnitude. At lower confidence levels the expected future discoveries increase to \$7.9 and \$98 trillion (1986) for the 10% and 1% confidence levels, respectively. It must be stressed that the objective of the assessment was only to rank the land base, not estimate the value of the resources it contained. The resource values generated by the assessment are only of value in generating the relative ranking of the land base.

Examination of these values on a regional basis shows considerably more variability. The ratio of estimated future discoverable resource values over discovered resource values is 3.1 for the province as a whole. This ratio for individual regions varies from a low of 1.14 for the Thompson-Okanagan region to a high of 21.13 for the Queen Charlotte Islands. These values may be used as a rough measure of a region's relative historic mineral discovery success. Many factors influence the value of this ratio but in general it illustrates the regional disparity in discoveries for whatever reason.

Figure 28. Table illustrating the regional and provincial values of discovered metallic mineral resources relative to the estimated discoverable metallic mineral resources at various estimation confidence levels. All dollar values are in 1986 Canadian dollars with conversions based on the Canadian Consumer Price Index.

In addition, we can examine the acceptance and precision of the estimation process itself. The use of expert probabilistic estimations for resource evaluation has a relatively long history. Many studies have been preformed and the methodology continues to be used. Like this study, these other estimation studies will not have been compared to the true resource value because that value is not known. However, the fact that the methodology continues to be employed in various jurisdictions for similar purposes implies that it is the best available at this time. Precision is the following of a precise set of rules. In this case the consistent adherence to the prescribed methodology steps and rules throughout the project has resulted in a precise evaluation. Use of consistent and complete input data sets has also contributed to the consistent application of the analysis across the province.

The mineral resource assessment of British Columbia can then be characterized as a very precise evaluation of unknown absolute discoverable deposit or commodity accuracy. But the requirement of the study was not to quantify the mineral resource of the province but to produce a relative ranking of the mineral potential of the province. A relative ranking is a much easier goal to achieve than an absolute value. If the evaluation process is uniformly applied and good precision of process is achieved even with very poor accuracy the relative ranking will be unaffected. Again we will never know if the relative ranking is correct but an accurate ranking is much more attainable than an accurate estimate of the number of new deposits to be found or absolute value of a tract.

Use in Economic Impact Assessments

The Mineral Resource Assessment provides a relative ranking of the land base of the province with respect to their estimated resource potential. This ranking provided the required input into the land use planning process for which it was designed. However, in land use planning exercises often the more important question is what resource is more important to society. The relative ranking of the land base resulting from the Mineral Resource Assessment does not address the question of relative importance to society of resources such as minerals, forestry, critical wildlife habitat or tourism potential. The relative importance of these general resource values is very fluid, changing from time to time and place to place.

Assessing the potential economic and environmental impact of developing and exploring for mineral deposits can convert some of the results coming from the Mineral Resource Assessment into terms more familiar to the land use planners and society as a whole. The estimated number of potential future mineral deposit discoveries can be used to provide values for the economic and environmental impact on society of alienating a particular tract of land. It is possible to fairly accurately determine the economic benefits accruing to society through tax revenues, employment and economic development associated with the expected development of virtually any deposit type of a given size and grade in a particular region of the

province. It is also equally straightforward to assess the environmental impact resulting from the expected development of such a deposit. In addition to the impact of developing a deposit, the economic and environmental effects of exploring for the deposit must be considered. While an economically feasible deposit is required to develop a mine and generate the associated economic and environmental impacts, only the hope of finding an economic deposit is required to generate mineral exploration activity and its associated impacts.

The results of the estimation workshops provide probabilistic estimates of the number of potential new deposit discoveries of each type in each resource assessment tract. The question that arises is how best to portray the results of the Mineral Resource Assessment into realistic portrayals of economic and environmental impacts. It is not possible to pick a specific probability level of new deposit discovery and say that portion of the estimated potential new discoveries would result in new discoveries. Only the 100 percent confidence level can be treated in this manner. Any effort to pick a particular probability level and consider any number of deposits with a great confidence of potential discovery will significantly overestimate the impacts.

The preferred method of presenting the economic and environmental impacts in a particular tract would be as probability distributions in the same manner as the number of potential deposits are described. Just as a given deposit type is represented by probability distributions of its commodity grade and tonnage based on real examples, a variety of economic and environmental impacts could be compiled for various mining scenarios. Possible variables to be included in the mine impact models may be capital cost of the project, person years of employment and economic multiplier effects. Using a Monte Carlo simulator, similar to the Mark3B, the output of combining the probabilities of the expected number of deposits and the probabilities of the various mine impact model parameters, would be the expected probabilities of the person years of employment, project capital cost and economic multiplier factor. With these parameters other economic variables such as tax revenues and secondary employment can be calculated. In the same manner environmental impact models with variables such as disturbed area, reclamation

costs and various impact values could be predicted. In this way the impacts are represented as probability ranges rather than picking a single value and then trying to justify that single confidence level. Again, great care must be taken to adequately explain the meaning of the determined values. For example, most people are familiar with getting probability of precipitation values in their daily weather forecasts but without reference to a detailed description of the exact meaning of this value a variety of interpretations are common among lay people.

An additional critical probability that must be considered to provide realistic values from such a modeling exercise is the probability distribution that given a deposit of a specific size is actually discovered what is the probability that it will be brought into production. Variables that would have to be modeled in this segment would be things such as commodity prices, availability of financing and regulatory hurdles. The results of modeling all these probabilities will be a very small chance of a mine actually being developed in any given tract. This is reality. But the resulting values will now be parameters that may be more understandable to the land use planners and easier to equate to other resource values being considered.

CHAPTER 7**SUMMARY**

The need to produce Mineral Resource Assessments was driven by the government's Protected Areas Strategy (PAS), which planned to double the protected areas in the province by the year 2000. The MRAs were necessary to provide fundamental information to help planning groups evaluate resource values in each of the planning regions and decide which areas should be recommended for protection.

At the outset of the program, a planning workshop led to decisions that the assessments would be quantitative, the land base would be ranked, expert industry and government input would be sought, and the information would be made easily accessible and in digital format.

The Mineral Potential Project began by making 1:250 000 scale geological compilations of high priority planning regions and progressed to compilations for all 9 regions. This up to date geology provided the fundamental control for all MRA evaluations. Other valuable databases that were available at the assessment workshops included MINFILE, exploration assessment reports, regional geochemical survey data, geophysical data, descriptive mineral deposit profiles and digital deposit models. Work was scheduled in concert with the regional planning processes over the 6-year life of the Mineral Potential Project.

The geology compilers defined resource assessment tracts. These were areas with similar geology at 1:250 000 scale, which were used as the assessment units. Assessments were then carried out on each tract with strong input from mineral industry experts. The process followed the USGS Three-Part Mineral Assessment Methodology (Singer, 1993) but with modifications to tailor it to the needs of the project. The most important changes were to eliminate the need for consensus among experts on their mineral potential estimates, resource assessment tract definition and to treat metallic and industrial mineral resources separately because their dependence on markets and infrastructure differ. The separation of metallic and industrial mineral methodologies meant that estimated undiscovered metallic resource assessments were based on gross in place value

(GIPV) and processed through the USGS Mark3B Mineral Resource Assessment Monte Carlo simulator. In contrast, undiscovered industrial mineral assessments were based on Relative Deposit Value Score (RDVS). RDVS considers commodity unit value, potential markets, deposit grade and tonnage, transportation costs, infrastructure and extraction costs.

The Mineral Potential Project evaluated only metallic and industrial mineral resources.

Results of the Mineral Resource Assessments were made available to the various planning processes in the form of maps and digital GIS files that portrayed the relative ranking of tracts within the assessment region being reviewed. Two ranking maps were prepared, one for metallic minerals and one for industrial minerals (Figure 27).

In addition to the final ranked tract maps, much of the preliminary information was also made available to the planners. For example the total estimated volume of commodity in each tract was calculated and is used to show commodity distributions. These values are contained in the tract summaries in Appendix 7. The number of deposits of each type expected to be found in each tract is also available. These values are presented in Appendix 8 and some are available for interactive viewing on the MapPlace website (www.mapplace.ca) through the Exploration Assistant (Kilby, 1999).

The mineral resource assessments were available to a variety of users with a range of industry and MRA exposure and understanding. It was essential that those using these analyses understood the assumptions that went into their production and their strengths and weaknesses. The major points that must continually be communicated to users of these analyses are:

- that the maps display relative ranking of the land base within a region. The lowest ranked tract does not necessarily have a low mineral potential, in fact it may have a very high potential for new discoveries, it is simply low relative to the other tracts in the area based on today's information.

- that the analyses are a snapshot in time. The relative rankings will change with time as new deposits are discovered, new deposit types are recognized, society's demand for commodities changes and our knowledge of the geology and deposit forming processes advance.
- that although the values predicted by the analysis are impossible to verify the relative rankings of tracts are useful for the current land use planning process and are the results of the best available methodology and information.

Problems were encountered in the use of the MRA maps and misunderstandings of the portrayed values resulted. Initially tracts were grouped into 10 classes, each containing about 10 per cent of the area of the planning region. The classes displayed on the maps were a simple partitioning of the tracts to facilitate easy visualization and the relative rankings of classes carried no intrinsic meaning. Unfortunately, there was a tendency, by user groups to lump the 10 tract classes into three classes and treat them as "high", "medium" and "low" mineral potential. This led to erroneous land use valuations and every attempt was made to discourage the practice. The tracts were simply ranked relative to each other in a given planning area. The assumption that they reflected a range from high to low mineral potential was wrong. They represented a range from highest to lowest mineral potential within a region. All tracts in the province are considered to have some mineral resource potential.

Mineral resource analysis is only one of the data sets that should be used to describe the importance of the mineral resource development in an area to the economy of the province. Other important information includes existing mineral land tenure, known mineral occurrences, and the socio-economic benefits of exploration and mining to the area.

The mineral resource assessments that we made are our best estimate of the relative future mineral discovery potential of an area based on our current knowledge. They were produced within tight deadlines for immediate use in land use planning exercises. Use of these assessments in the future without upgrading would be invalid. The maps are only as current and valid as the information they contain. New technology, new

geological information, new exploration ideas, new commodity uses and changing societal demands for commodities will all result in the current study results becoming dated and require a new assessment to be undertaken or the current study updated before the results are valid in future land use planning processes.

APPENDICES

APPENDIX 1

Example of a Descriptive Deposit Model - Sedimentary Exhalative Zinc-Lead-Silver

This appendix contains only one of the many deposit models used during the project. Other models are available for view online at

<http://www.em.gov.bc.ca/Mining/Geolsurv/MetallicMinerals/MineralDepositProfiles/>

SEDIMENTARY EXHALATIVE Zn-Pb-Ag

E14

by Don MacIntyre
British Columbia Geological Survey

MacIntyre, Don (1995): Sedimentary Exhalative Zn-Pb-Ag, in Selected British Columbia Mineral Deposit Profiles, Volume 1 - Metallics and Coal, Lefebure, D.V. and Ray, G.E., Editors, British Columbia Ministry of Energy of Employment and Investment, Open File 1995-20, pages 37-39.

IDENTIFICATION

SYNOMYS: Shale-hosted Zn-Pb-Ag; sediment-hosted massive sulphide Zn-Pb-Ag; Sedex Zn- Pb.

COMMODITIES (BYPRODUCTS): Zn, Pb, Ag, (minor Cu, barite).

EXAMPLES (British Columbia - Canada/International): Cirque, Sullivan, Driftpile; Faro, Grum, Dy, Vangorda, Swim, Tom and Jason (Yukon, Canada), Red Dog (Alaska, USA), McArthur River and Mt. Isa (Australia); Megen and Rammelsberg (Germany).

GEOLOGICAL CHARACTERISTICS

CAPSULE DESCRIPTION: Beds and laminations of sphalerite, galena, pyrite, pyrrhotite and rare chalcopyrite, with or without barite, in euxinic clastic marine sedimentary strata.. Deposits are typically tabular to lensoidal in shape and range from centimetres to tens of metres thick. Multiple horizons may occur over stratigraphic intervals of 1000 m or more.

TECTONIC SETTING: Intracratonic or continental margin environments in fault-controlled basins and troughs. Troughs are typically half grabens developed by extension along continental margins or within back-arc basins.

DEPOSITIONAL ENVIRONMENT / GEOLOGICAL SETTING: Restricted second and third order basins within linear, fault-controlled marine, epicratonic troughs and basins. There is often evidence of penecontemporaneous movement on faults bounding sites of sulphide deposition. The depositional environment varies from deep, starved marine to ? shallow water restricted shelf.

AGE OF MINERALIZATION: The major metallogenic events are Middle Proterozoic, Early Cambrian, Early Silurian and Middle to Late Devonian to Mississippian. The Middle Proterozoic and Devonian-Mississippian events are

recognized worldwide. In the Canadian Cordillera, minor metallogenic events occur in the Middle Ordovician and Early Devonian.

HOST/ASSOCIATED ROCK TYPES: The most common hostrocks are those found in euxinic, starved basin environments, namely, carbonaceous black shale, siltstone, cherty argillite and chert. Thin interbeds of turbiditic sandstone, granule to pebble conglomerate, pelagic limestone and dolostone, although volumetrically minor, are common. Evaporites, calcareous siltstone and mudstone are common in shelf settings. Small volumes of volcanic rocks, typically tuff and submarine mafic flows, may be present within the host succession. Slump breccia, fan conglomerates and similar deposits occur near synsedimentary growth faults. Rapid facies and thickness changes are found near the margins of second and third order basins. In some basins high-level mafic sills with minor dikes are important.

DEPOSIT FORM: These deposits are stratabound, tabular to lens shaped and are typically comprised of many beds of laminae of sulphide and/or barite. Frequently the lenses are stacked and more than one horizon is economic. Ore lenses and mineralized beds often are part of a sedimentary succession up to hundreds of metres thick. Horizontal extent is usually much greater than vertical extent. Individual laminae or beds may persist over tens of kilometres within the depositional basin.

TEXTURE/STRUCTURE: Sulphide and barite laminae are usually very finely crystalline where deformation is minor. In intensely folded deposits, coarser grained, recrystallized zones are common. Sulphide laminae are typically monomineralic.

ORE MINERALOGY (Principal and subordinate): The principal sulphide minerals are pyrite, pyrrhotite, sphalerite and galena. Some deposits contain significant amounts of *chalcopyrite*, but most do not. Barite may or may not be a major component of the ore zone. Trace amounts of *marcasite*, *arsenopyrite*, *bismuthinite*, *molybdenite*, *enargite*, *millerite*, *freibergite*, *cobaltite*, *cassiterite*, *vallerite* and *melnikovite* have been reported from these deposits. These minerals are usually present in very minor amounts.

ALTERATION MINERALOGY: Alteration varies from well developed to nonexistent. In some deposits a stockwork and disseminated feeder zone lies beneath, or adjacent to, the stratiform mineralization. Alteration minerals, if present, include silica, tourmaline, carbonate, albite, chlorite and dolomite. They formed in a relatively low temperature environment. Celsian, Ba-muscovite and ammonium clay minerals have also been reported but are probably not common.

ORE CONTROLS: Favourable sedimentary sequences, major structural breaks, basins.

GENETIC MODEL: The deposits accumulate in restricted second and third order basins or half grabens bounded by synsedimentary growth faults. Exhalative centres occur along these faults and the exhaled brines accumulate in adjacent seafloor depressions. Biogenic reduction of seawater sulphate within an anoxic brine pool is believed to control sulphide precipitation.

ASSOCIATED DEPOSIT TYPES: Associated deposit types include carbonate-hosted sedimentary exhalative, such as the Kootenay Arc and Irish deposits (E13), bedded barite (E17) and iron formation (F10).

EXPLORATION GUIDES

GEOCHEMICAL SIGNATURE: The deposits are typically zoned with Pb found closest to the vent grading outward and upward into more Zn-rich facies. Cu is usually found either within the feeder zone or close to the exhalative vent. Barite, exhalative chert and hematite-chert iron formation, if present, are usually found as a distal facies. Sediments such as pelagic limestone interbedded with the ore zone may be enriched in Mn. NH₃ anomalies have been documented at some deposits, as have Zn, Pb and Mn haloes. The host stratigraphic succession may also be enriched in Ba on a basin-wide scale.

GEOPHYSICAL SIGNATURE: Airborne and ground geophysical surveys, such as electromagnetics or magnetics should detect deposits that have massive sulphide zones, especially if these are steeply dipping. However, the presence of graphite-rich zones in the host sediments can complicate the interpretation of EM conductors. Also, if the deposits are flat lying and comprised of fine laminae distributed over a significant stratigraphic interval, the geophysical response is usually too weak to be definitive. Induced polarization can detect flat-lying deposits, especially if disseminated feeder zones are present.

OTHER EXPLORATION GUIDES: The principal exploration guidelines are appropriate sedimentary environment and stratigraphic age. Restricted marine sedimentary sequences deposited in an epicratonic extensional tectonic setting during the Middle Proterozoic, Early Cambrian, Early Silurian or Devon-Mississippian ages are the most favourable.

ECONOMIC FACTORS

GRADE AND TONNAGE: The median tonnage for this type of deposit worldwide is 15 Mt, with 10 % of deposits in excess of 130 Mt (Briskey, 1986). The median grades worldwide are Zn - 5.6%, Pb - 2.8% and Ag - 30 g/t. The Sullivan deposit, one of the largest deposits of this type ever discovered, has a total size of more than 155 Mt grading 5.7% Zn, 6.6% Pb and 7 g/t Ag. Reserves at the Cirque are 32.2 Mt grading 7.9% Zn, 2.1% Pb and 48 g/t Ag.

ECONOMIC LIMITATIONS: The large, near-surface deposits are amenable to high volume, open pit mining operations. Underground mining is used for some deposits.

IMPORTANCE: Sedimentary exhalative deposits currently produce a significant proportion of the world's Zn and Pb. Their large tonnage potential and associated Ag values make them an attractive exploration target.

APPENDIX 2

Digital map unit descriptive codes

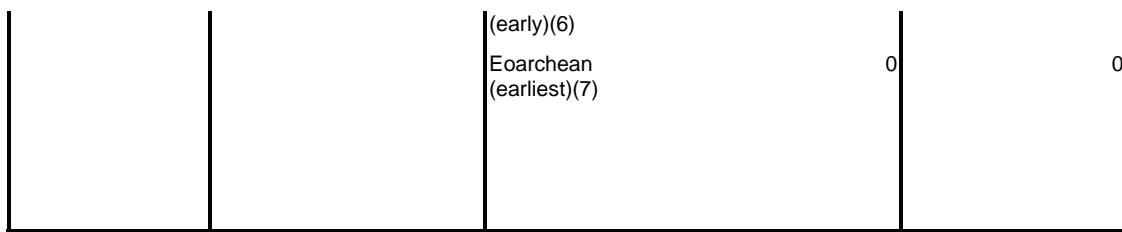

These numerical codes which were used to describe the character of individual map units are fundamental to the ability to query the compiled geology of the province with respect to characteristics such as lithology, age and terrane. The compiled geology is available online for query using these codes through the Exploration Assistant at <http://www.mapplace.ca/>.

● ● ●

These two files provide information to the Mark3B Monte Carlo Simulator. One file displays the simulator's commodity codes and associated commodity name. The partial listing of the .BEM file shows the three possible mineral combination suites that are available for this model. The Mark3B simulator uses the mineral associations and probability distributions in the file. They are generated prior to running the simulator.

APPENDIX 4

Commodity 1986 dollar value listing

The dollar per tonne values displayed for each commodity are a 10-year (1981-1990) average price for the commodity. Dollar value conversions were based on the Canadian Consumer Price Index.

Commodity	Price	Commodity	Price
Aluminum Oxide	\$100.00	Lithium	\$7,391.00
Aluminum Silicate	\$135.00	Magnesite	\$19.58
Andesite	\$146.34	Magnetite	\$40.00
Anhydrite	\$11.35	Manganese	\$167.28
Antimony	\$5,285.76	Marble	\$93.00

APPENDIX 7

Tract Wise Mineral Resource Assessment Results Display

The estimated number of deposits shown for each confidence level is based on a weighted average of the participating estimators and are interpolated from the estimators actual values to the five discrete confidence values required by the Mark3B simulator.

APPENDIX 8

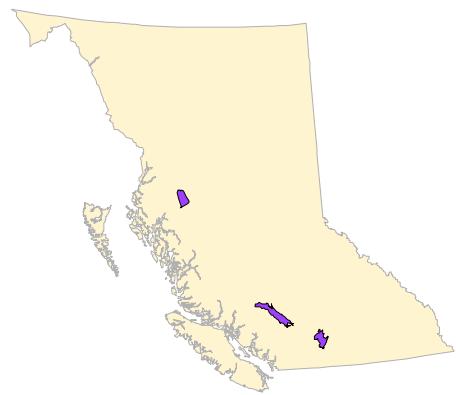

Deposit Type Discovery Potential Maps

The maps displayed in this appendix were produced with the aid of the Exploration Assistant map view in the MapPlace at <http://www.mappleplace.ca>.

**Deposit Name: Laterite Fe
Model Code: (B01/B1)**

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

**Deposit Name: Bauxite
Model Code: (B04/B5)**

50% Confidence of One Deposit in:

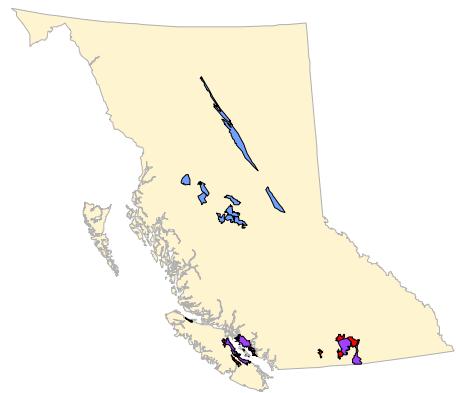

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

**Deposit Name: Residual Kaolin
Model Code: (B05/B6)**

50% Confidence of One Deposit in:

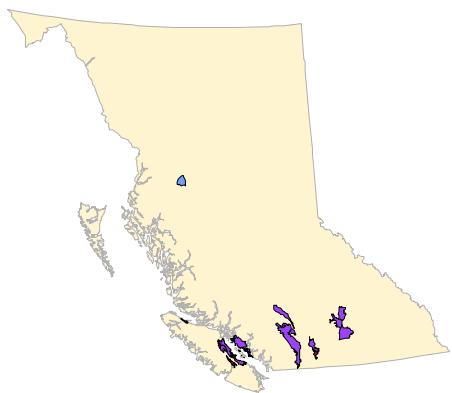

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

**Deposit Name: Fireclay
Model Code: (B06/B7)**

50% Confidence of One Deposit in:

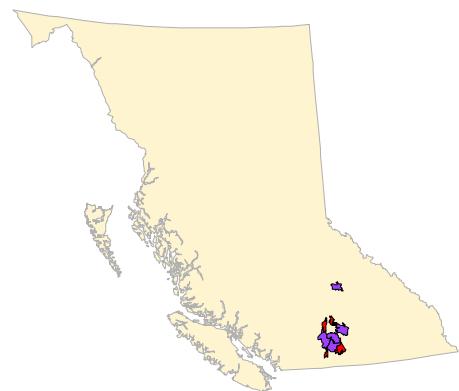

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Surficial U
Model Code: (B08/B8)

50% Confidence of One Deposit in:

- <100,000 Ha
- 100,000 - 1,000,000 Ha
- >1,000,000 Ha

Deposit Name: Marl
Model Code: (B11/Marl)

50% Confidence of One Deposit in:

- <100,000 Ha
- 100,000 - 1,000,000 Ha
- >1,000,000 Ha

Deposit Name: Pozzolan
Model Code: (B?/PORZZOL)

50% Confidence of One Deposit in:

- <100,000 Ha
- 100,000 - 1,000,000 Ha
- >1,000,000 Ha

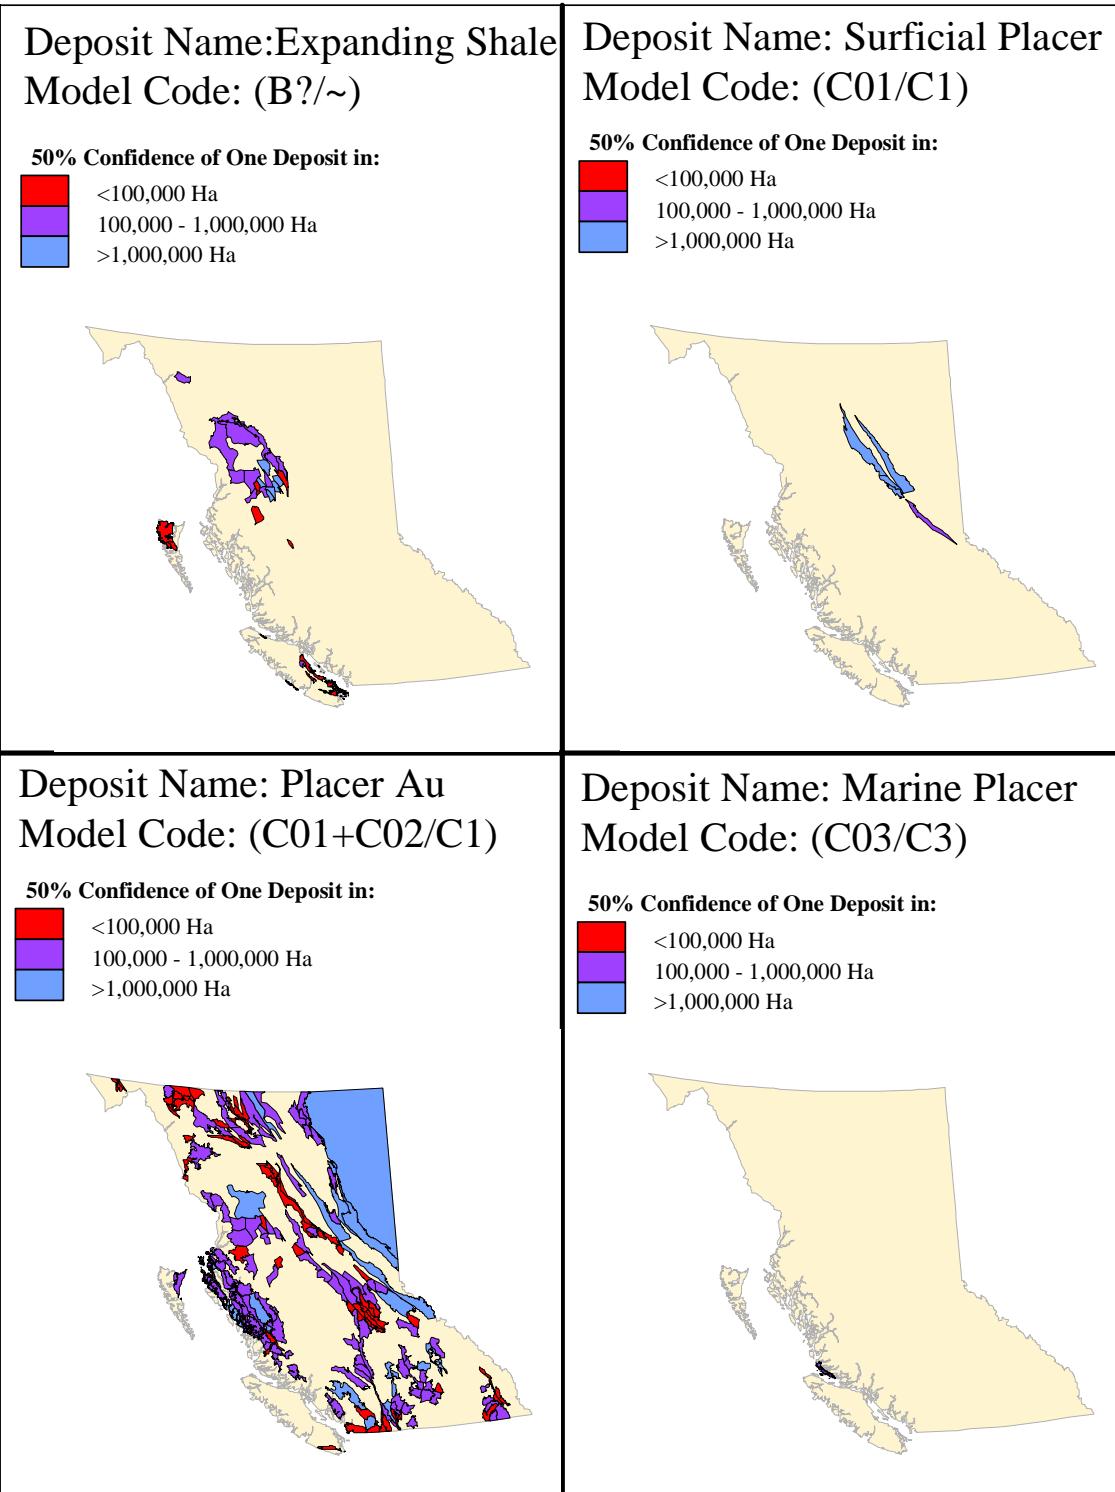

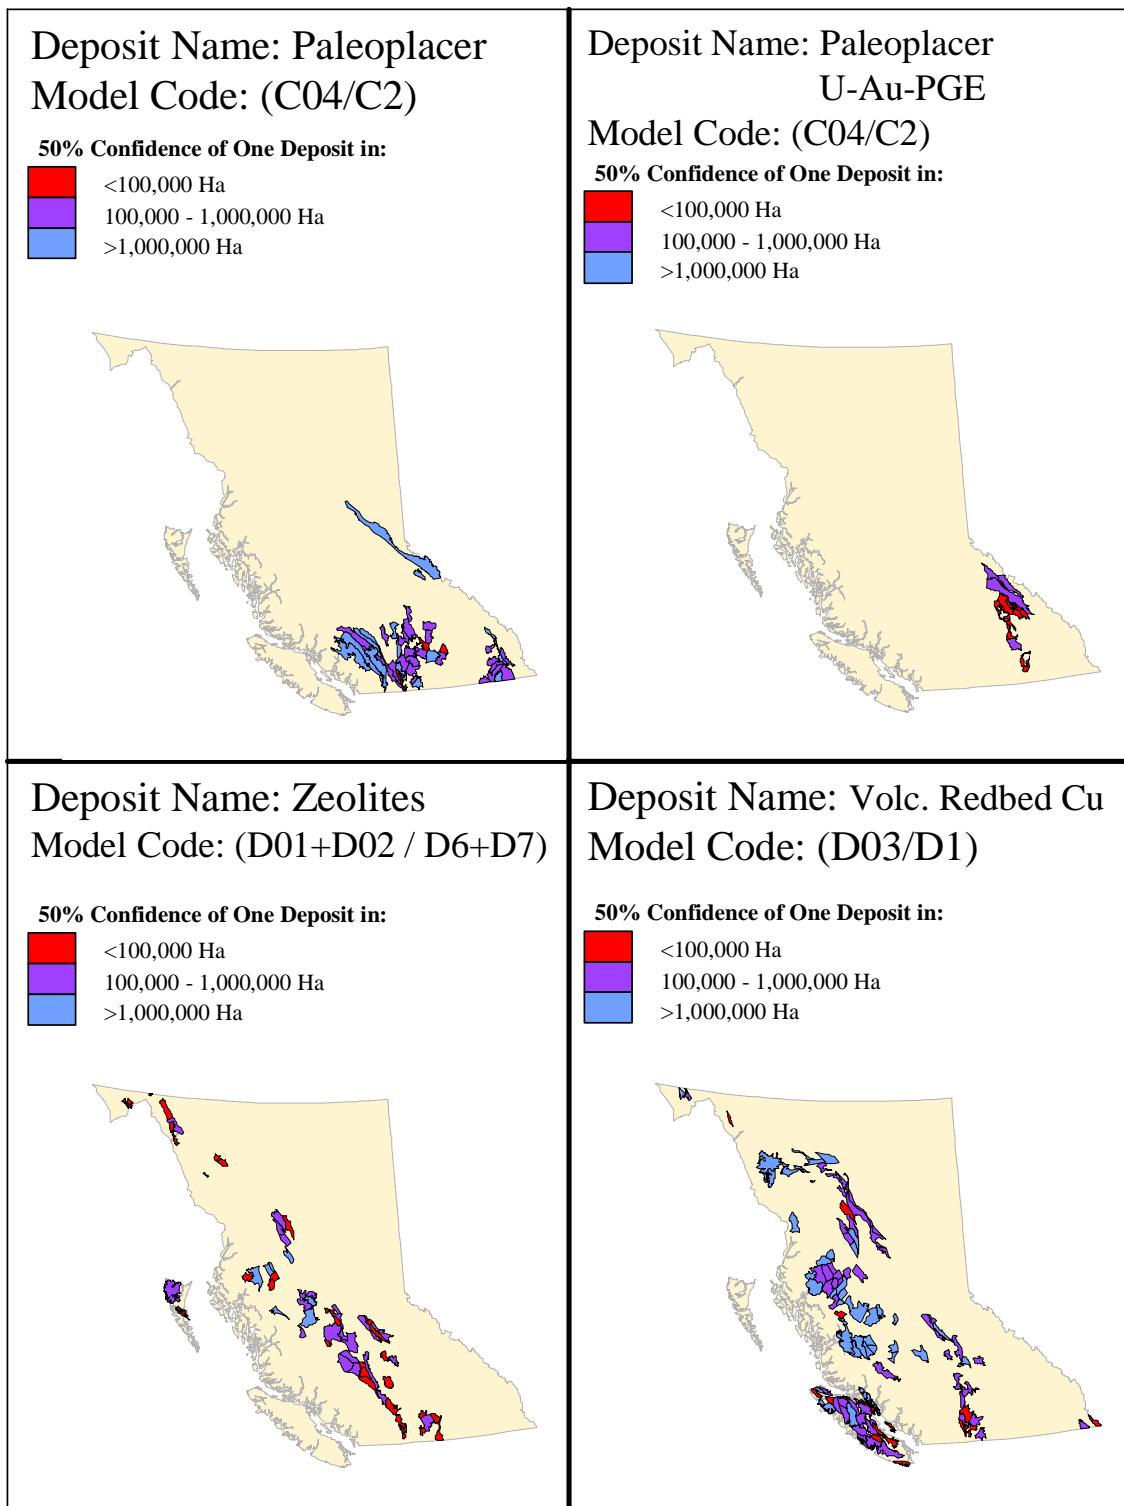

Deposit Name: Fullers Earth
Model Code: (B?/Fullers)

50% Confidence of One Deposit in:

- <100,000 Ha
- 100,000 - 1,000,000 Ha
- >1,000,000 Ha

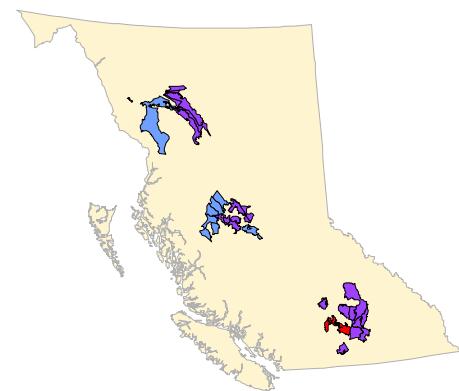

Deposit Name: Basal U
Model Code: (D04/D3)

50% Confidence of One Deposit in:

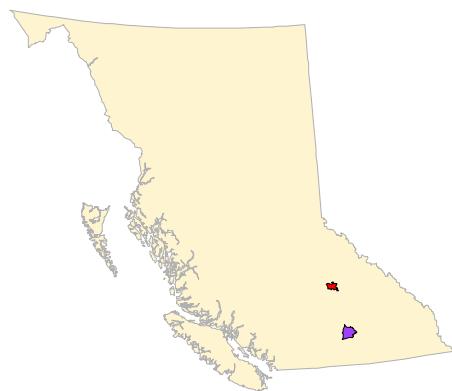

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Volc. U
Model Code: (D06/D5)

50% Confidence of One Deposit in:

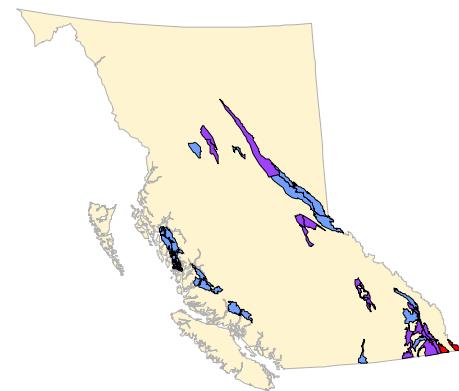

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sed. Hosted Cu
Model Code: (E04/E4b)

50% Confidence of One Deposit in:

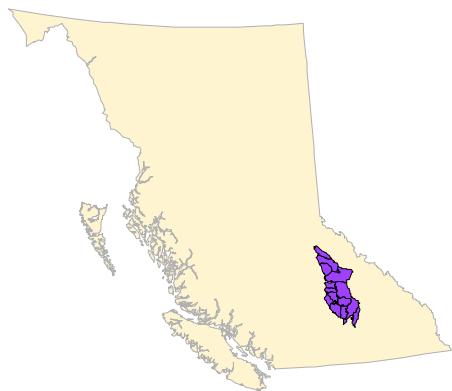

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sed. Hosted Cu
Model Code: (E04/D2)

50% Confidence of One Deposit in:

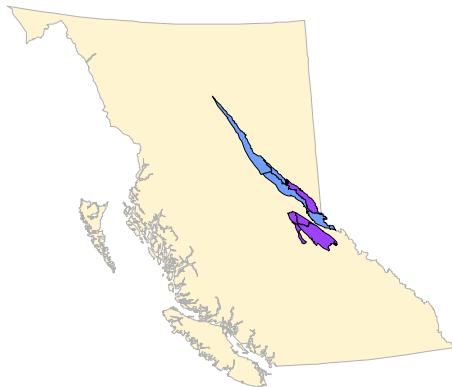

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sandstone Pb
Model Code: (E05/E7)

50% Confidence of One Deposit in:

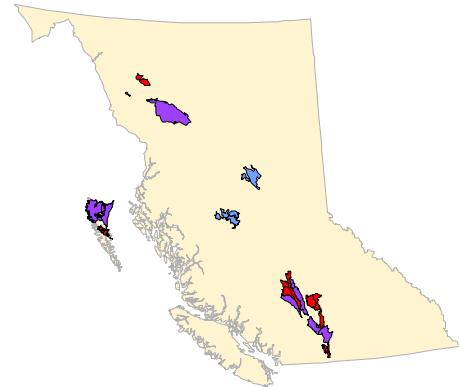

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Bentonite
Model Code: (E06/E9)

50% Confidence of One Deposit in:

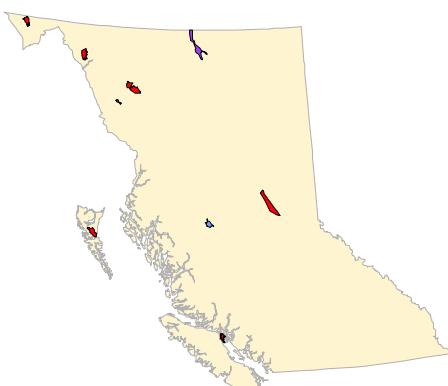

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sedimentary Kaolin
Model Code: (E07/E10+E10a)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sedimentary Clay
Model Code: (E07?/E10b)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Kaolinite
Model Code: (E07?/Kaolini)

50% Confidence of One Deposit in:

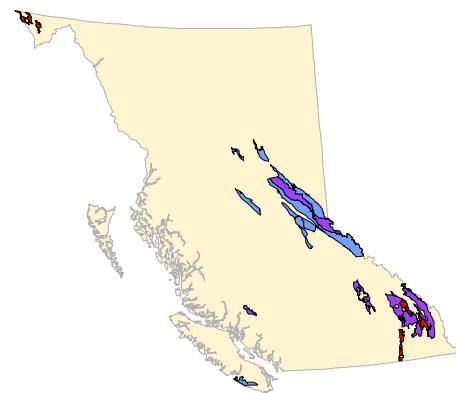

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Carbonate host talc
Model Code: (E08/E6b)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Talc
Model Code: (E08/R4+E6b)

50% Confidence of One Deposit in:

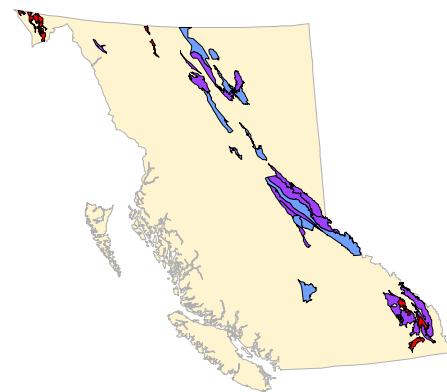

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

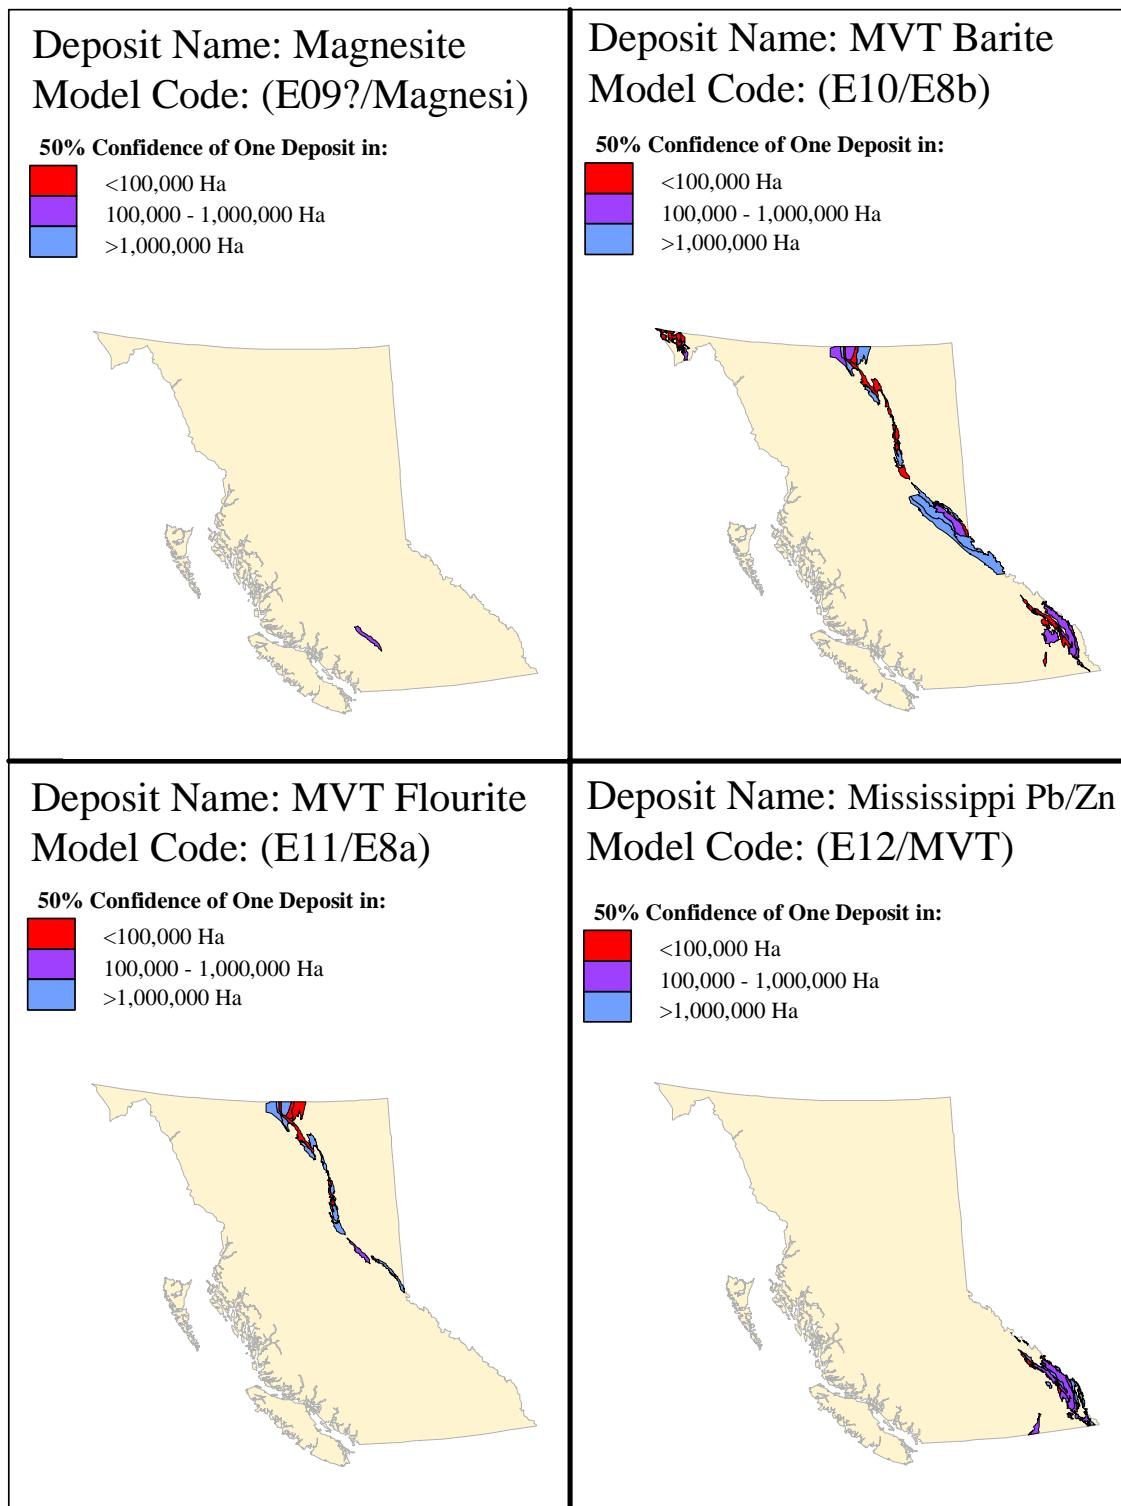

Deposit Name: Sparry Magnesite
Model Code: (E09/E6a)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

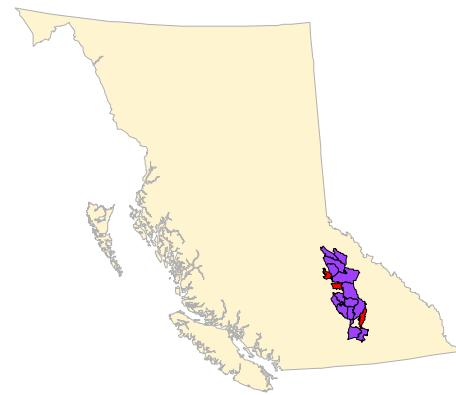

Deposit Name: MVT Pb/Zn
Model Code: (E12/E1+H2)

50% Confidence of One Deposit in:

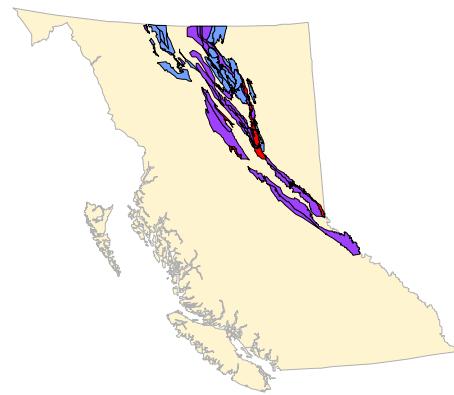

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: MVT Zn/Pb
Model Code: (E12/E1+E1a)

50% Confidence of One Deposit in:

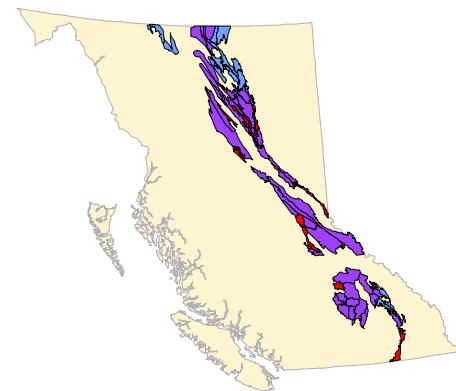

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Koot. Arc Zn/Pb
Model Code: (E13/E1b)

50% Confidence of One Deposit in:

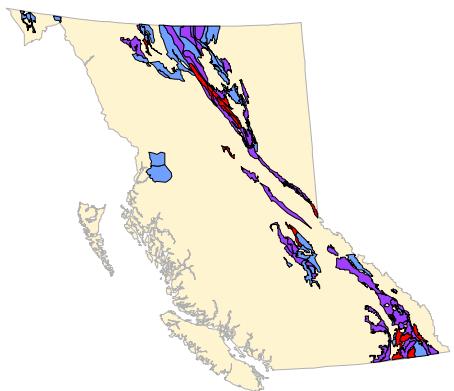

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sedex Zn/Pb/Ag
Model Code: (E14/H2a)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Blackbird Cu-Co
Model Code: (E15/H3)

50% Confidence of One Deposit in:

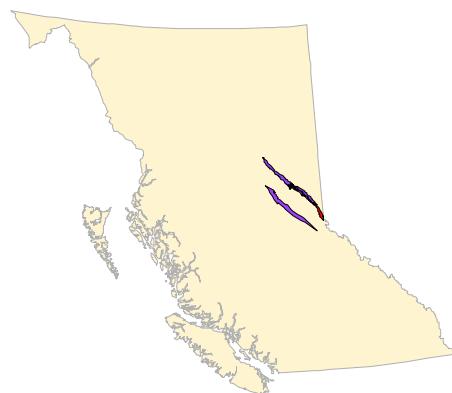

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sediment hosted Ni
Model Code: (E16/H1)

50% Confidence of One Deposit in:

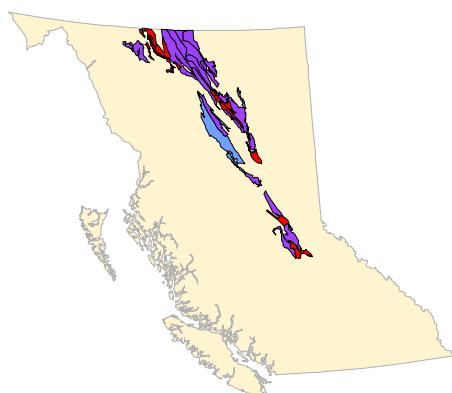

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sed. Hosted Barite
Model Code: (E17/F3)

50% Confidence of One Deposit in:

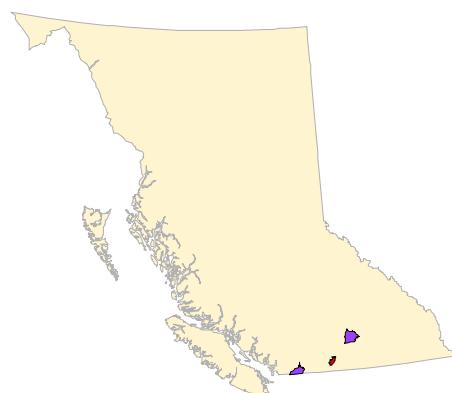

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Carbonate hosted Au-Ag
Model Code: (E?/E4)

50% Confidence of One Deposit in:

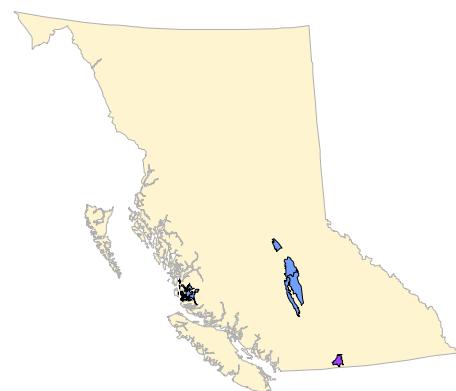

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

**Deposit Name: Sedimentary Mn
Model Code: (F01/F1)**

50% Confidence of One Deposit in:

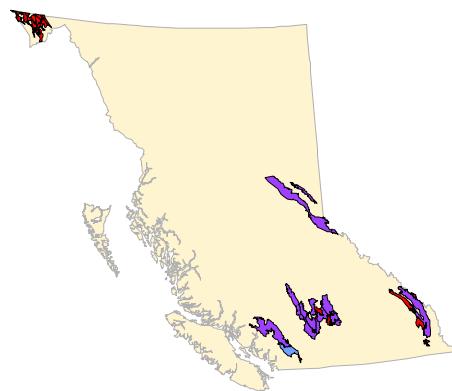

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

**Deposit Name: Bedded Gypsum /
Anhydrite
Model Code: (F02/F4a)**

50% Confidence of One Deposit in:

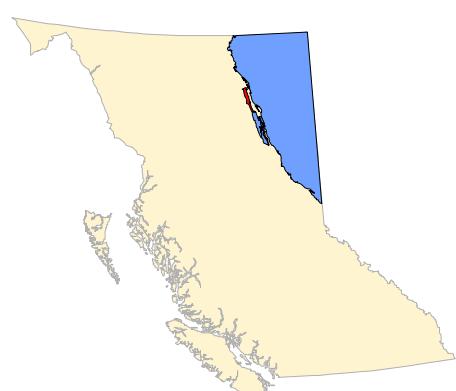

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

**Deposit Name: Gypsum-hosted
Sulphur
Model Code: (F03/F5)**

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

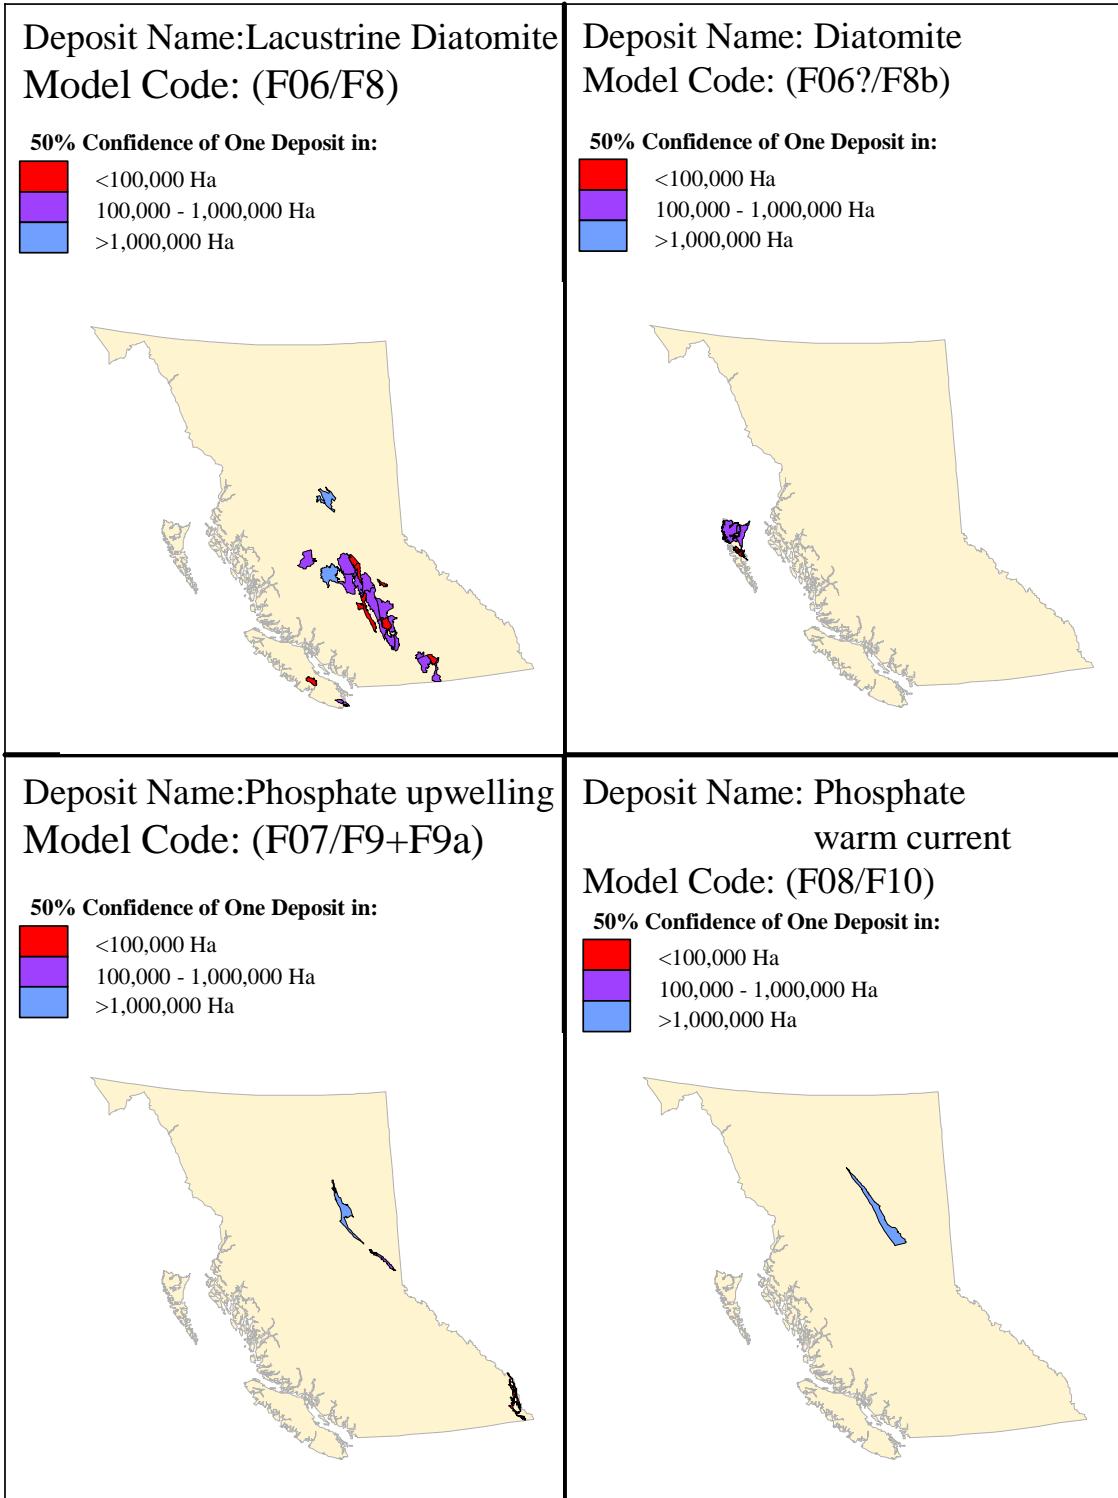

**Deposit Name: Bedded Celestite
Model Code: (F04/F6)**

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

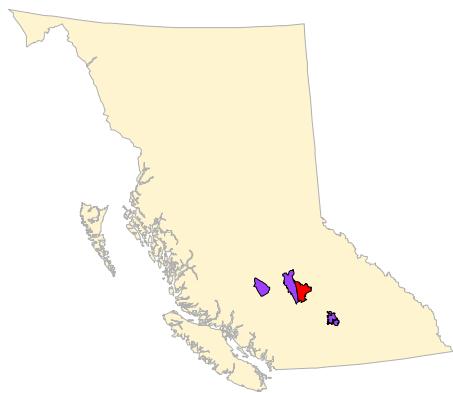

Deposit Name: Playas
Model Code: (F09/F11)

50% Confidence of One Deposit in:

- <100,000 Ha
- 100,000 - 1,000,000 Ha
- >1,000,000 Ha

Deposit Name: Salt
Model Code: (F09?/SALT)

50% Confidence of One Deposit in:

- <100,000 Ha
- 100,000 - 1,000,000 Ha
- >1,000,000 Ha

Deposit Name: Soda
Model Code: (F09?/SODA)

50% Confidence of One Deposit in:

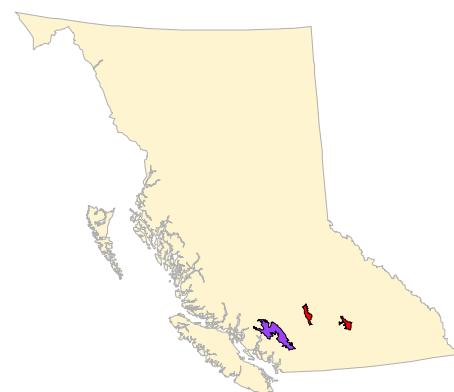

- <100,000 Ha
- 100,000 - 1,000,000 Ha
- >1,000,000 Ha

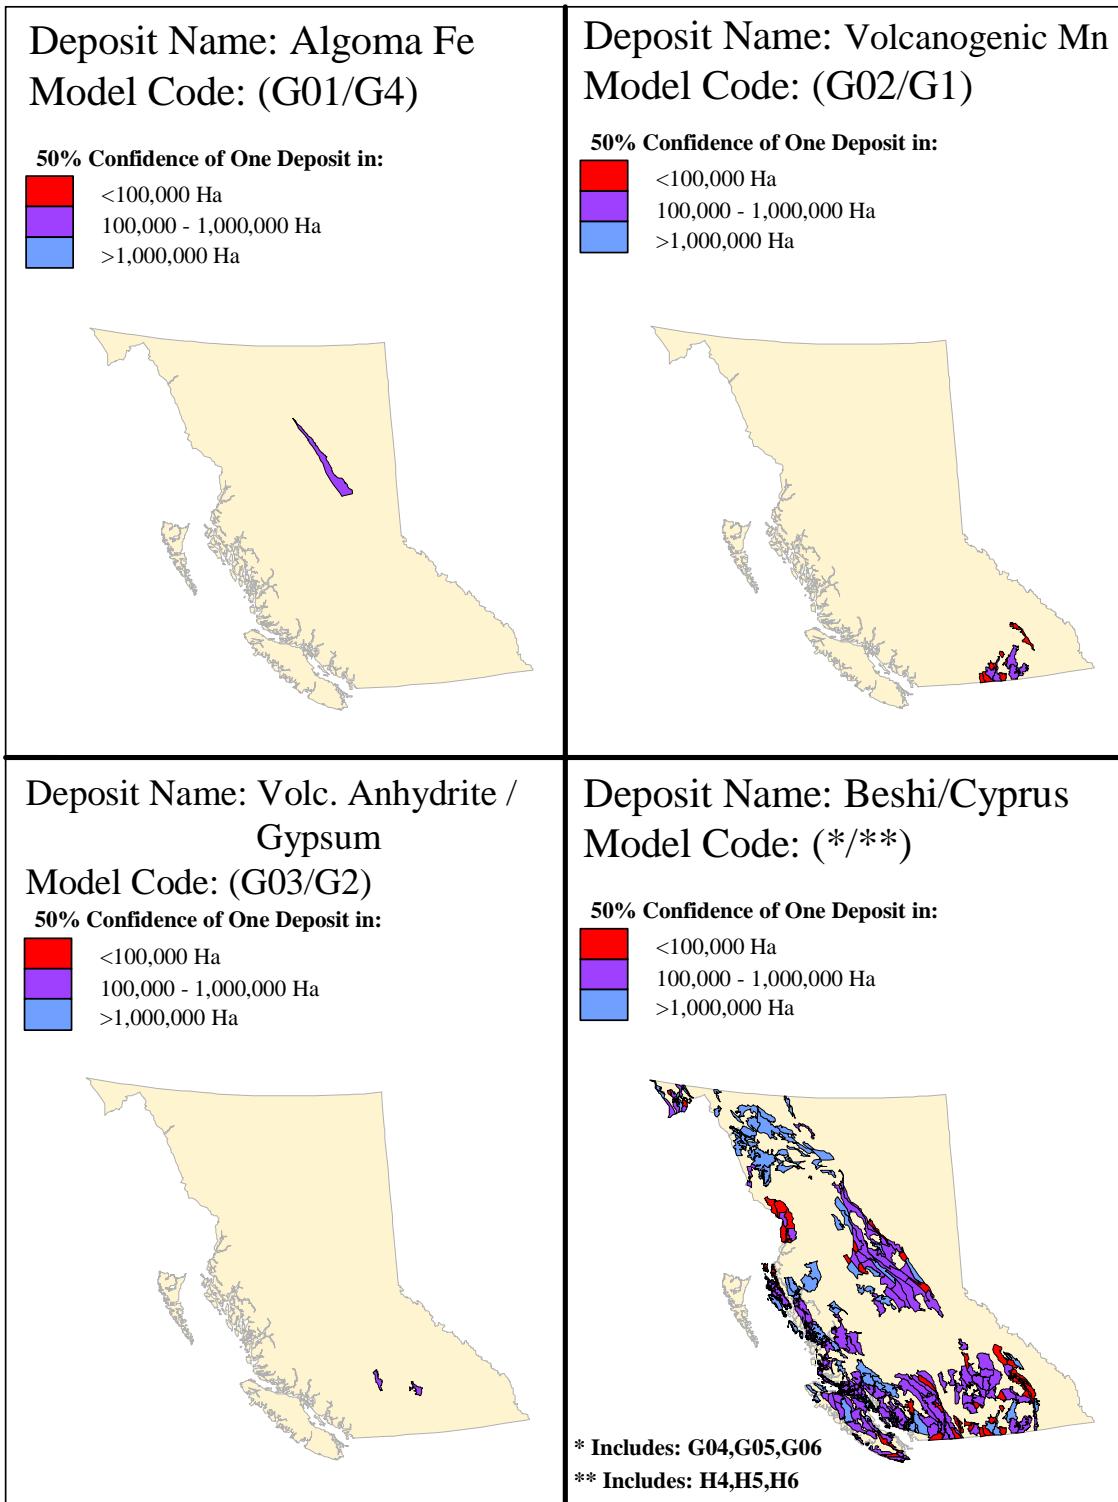

Deposit Name: Gypsum
Model Code: (F?/Gypsum)

50% Confidence of One Deposit in:

- <100,000 Ha
- 100,000 - 1,000,000 Ha
- >1,000,000 Ha

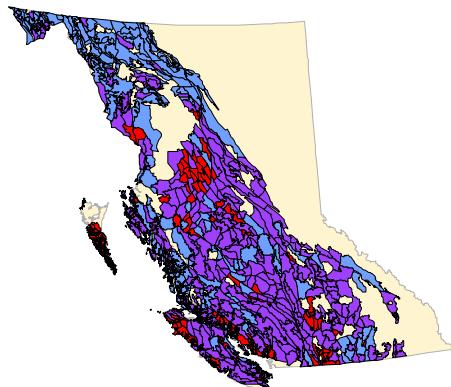

Deposit Name: Cyprus MS
Model Code: (G05/H6)

50% Confidence of One Deposit in:

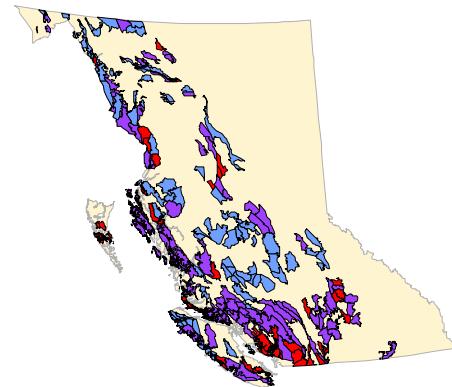

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Noranda/Kuroko
Model Code: (G06/H5)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sub. Hotspring
Ag-Au
Model Code: (G07/I1)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Hotspring Hg
Model Code: (H01/I3)

50% Confidence of One Deposit in:

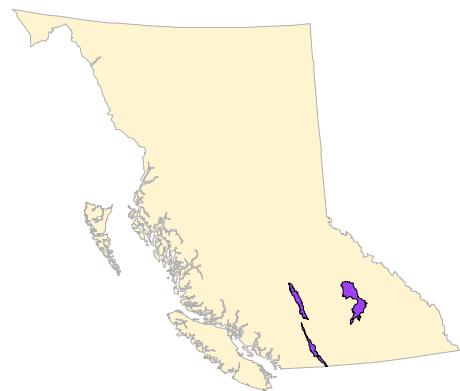

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Travertine
Model Code: (H01/I2)

50% Confidence of One Deposit in:

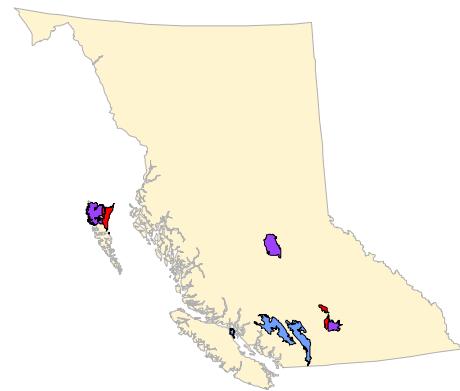

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Hot-Spring Au/Ag
Model Code: (H03/I4)

50% Confidence of One Deposit in:

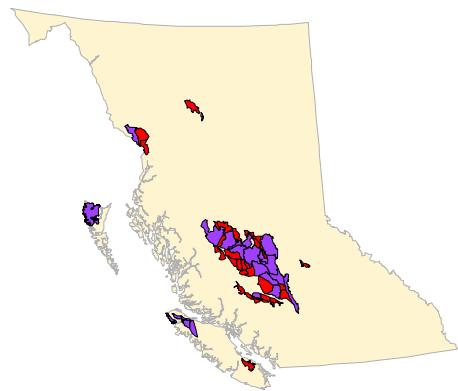

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Epithermal Au-Ag
High sulphidation
Model Code: (H04/I5)

50% Confidence of One Deposit in:

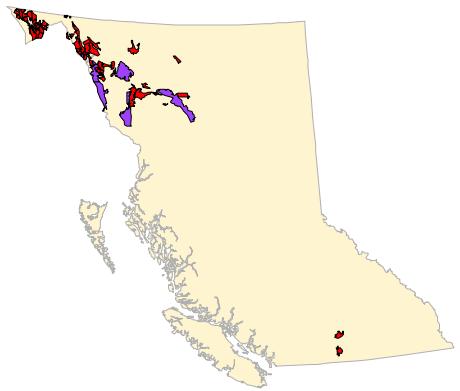

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

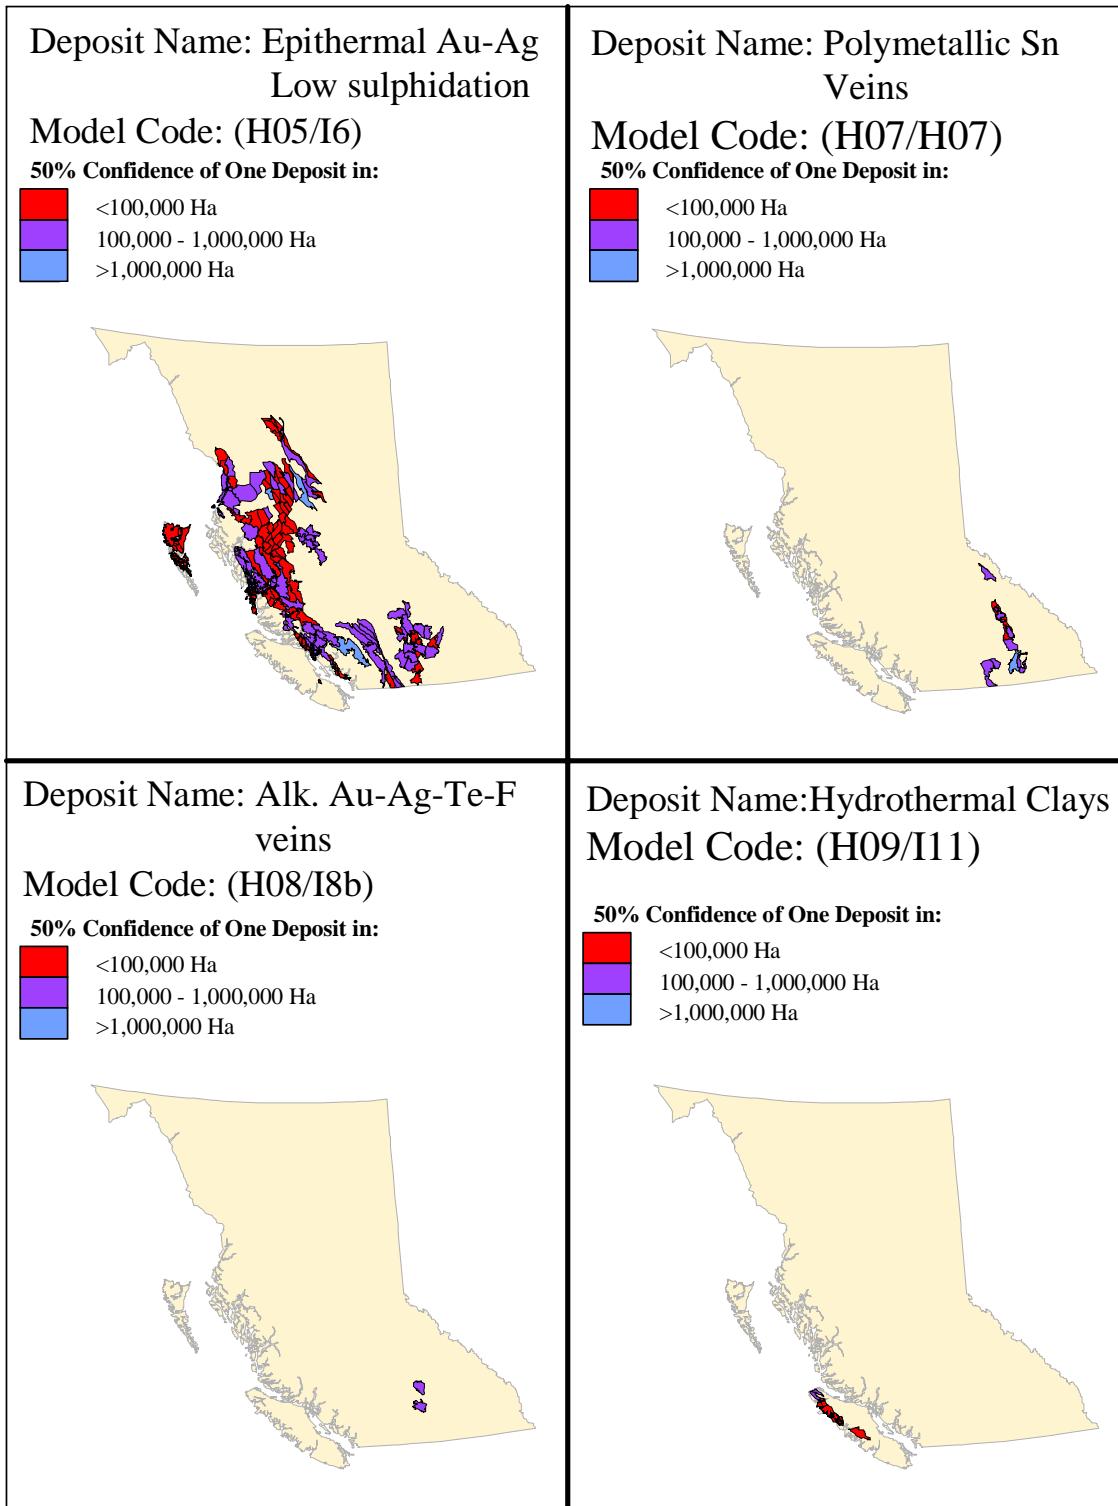

Deposit Name: Epithermal Au/Ag
Model Code: (H04+H05/I5+I6)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

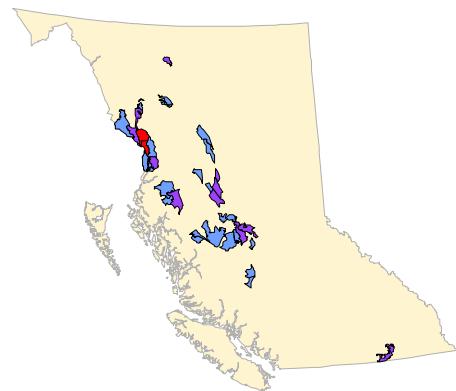

Deposit Name: Eskay Creek
Model Code: (H?/EC)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Talc Meta-Sed
Model Code: (H?/37n)

50% Confidence of One Deposit in:

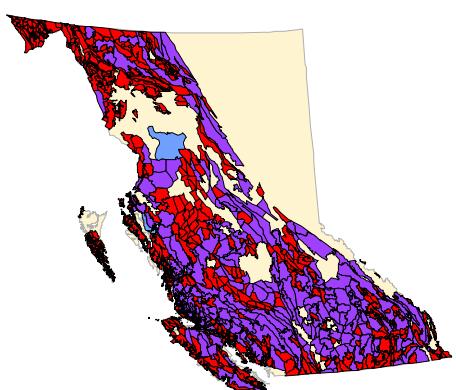

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Au-Quartz Vein
Model Code: (I01/J4+J4a)

50% Confidence of One Deposit in:

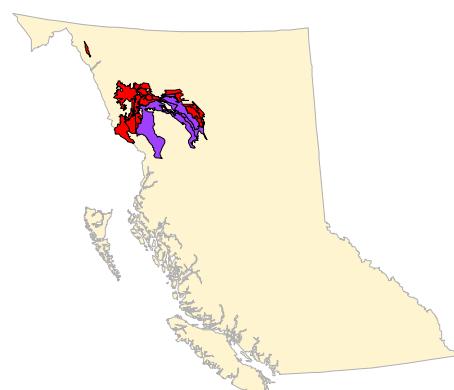

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

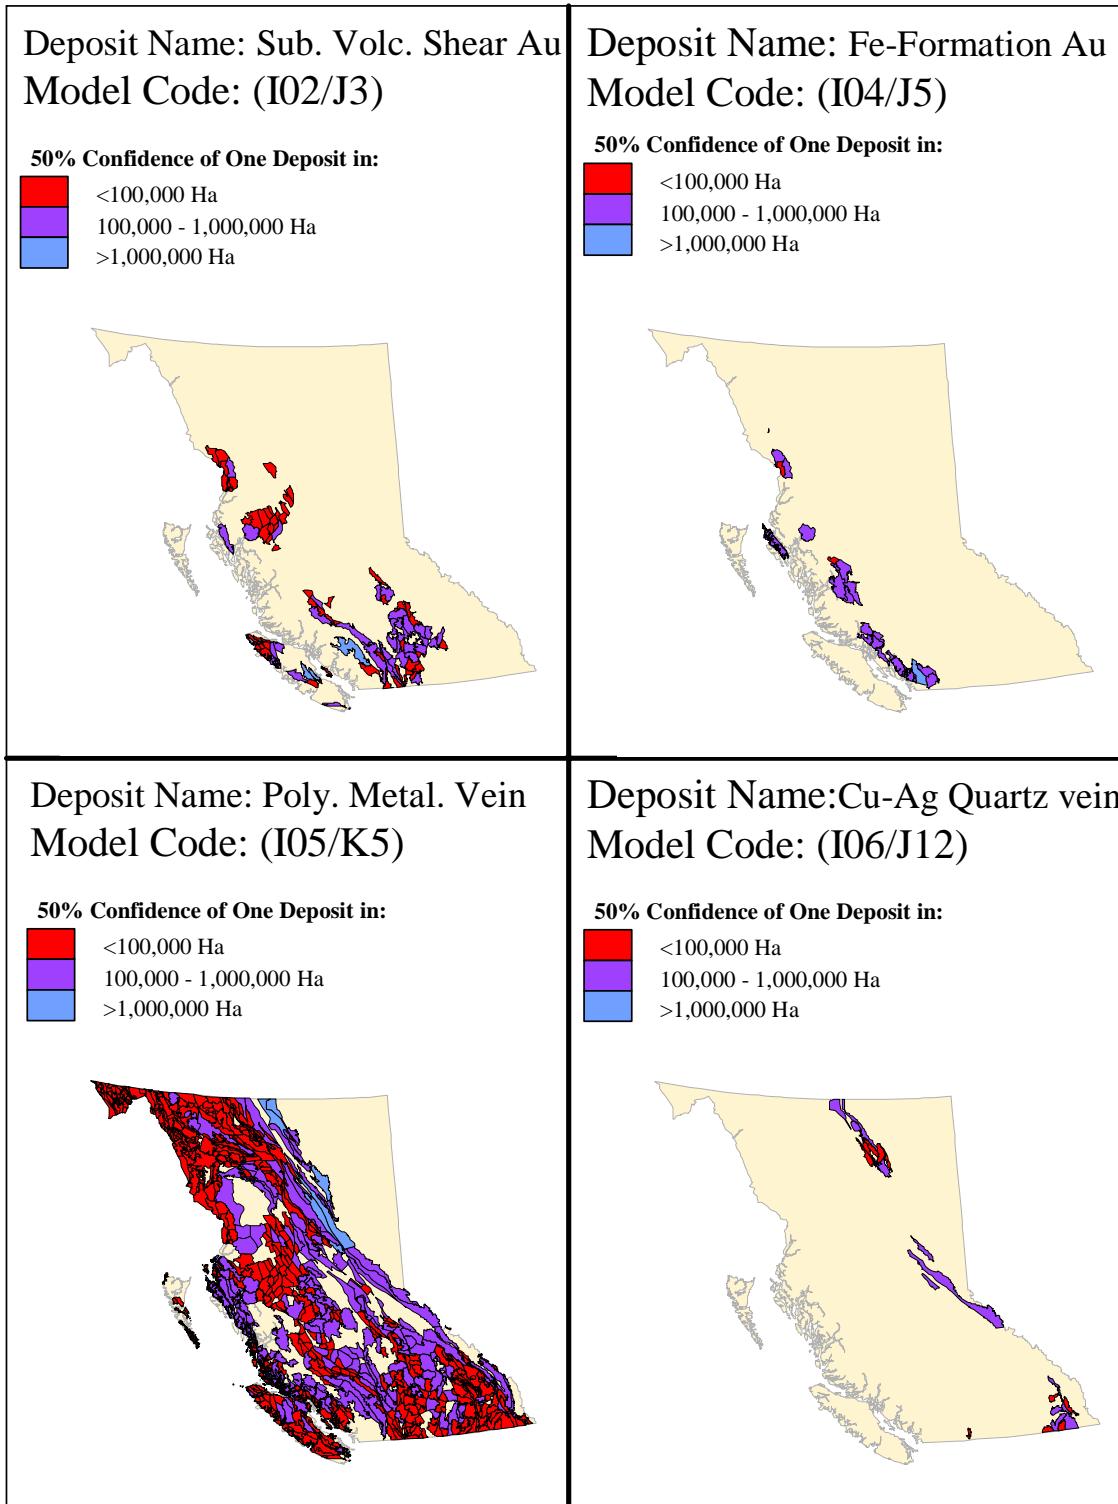

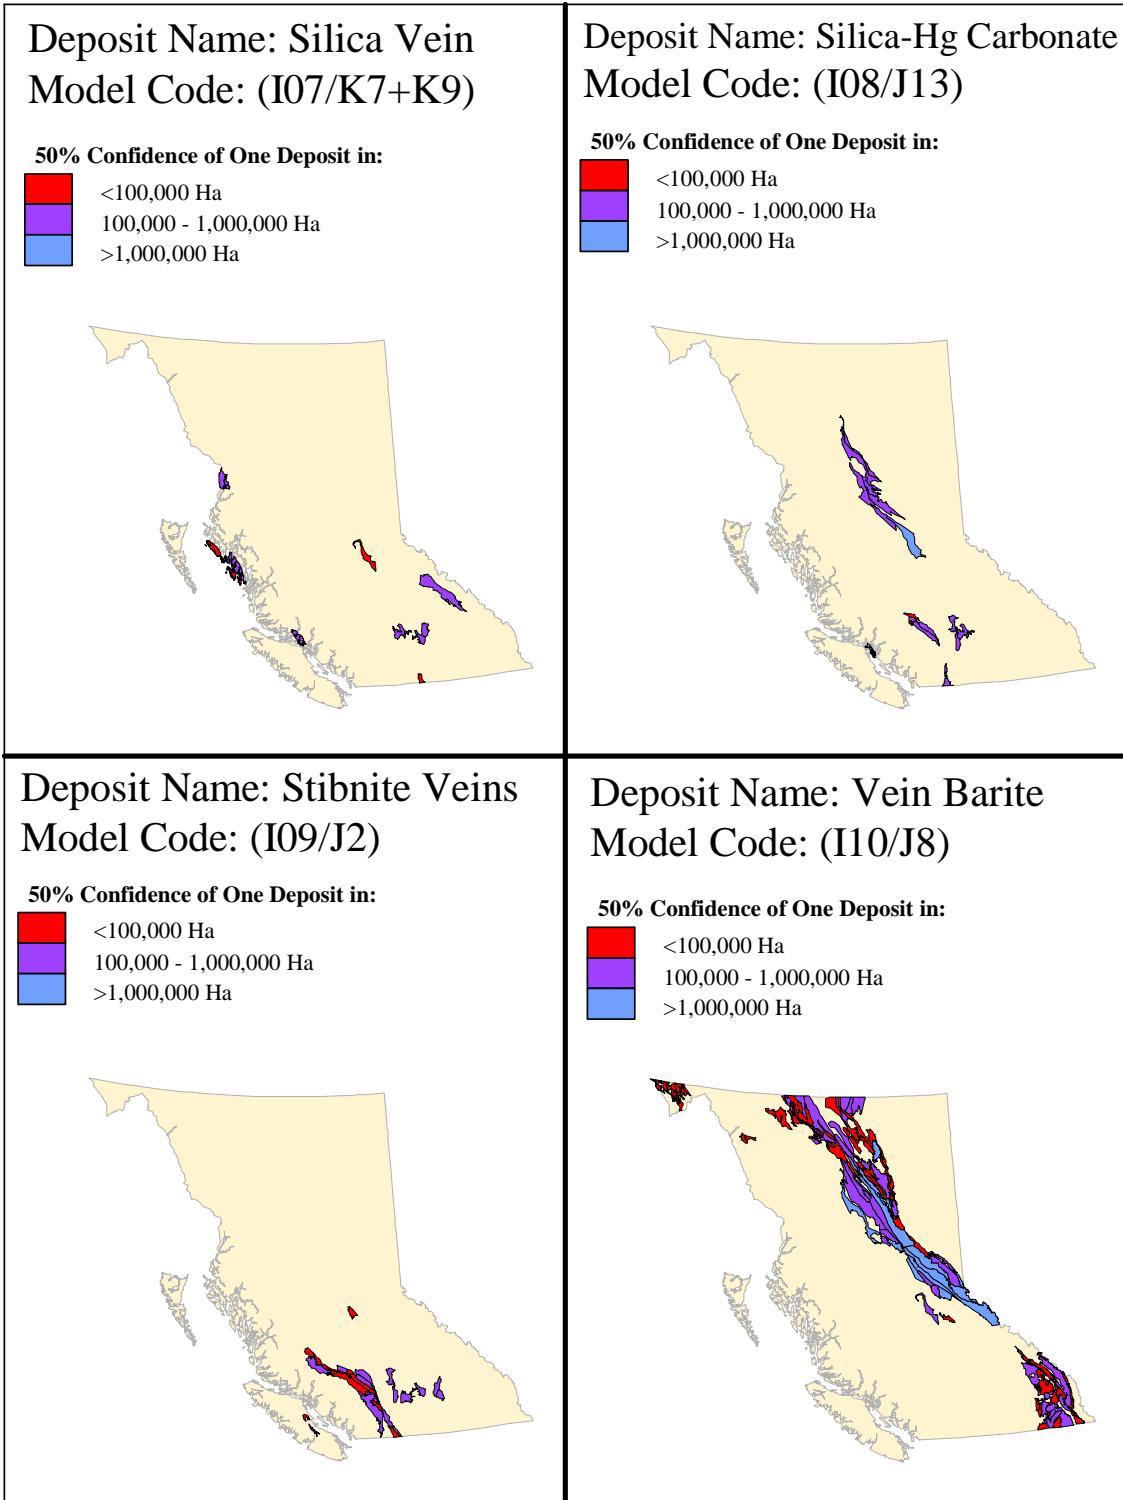

Deposit Name: Au Qtz veins &
shear hosted
Model Code: (I01+I02 / J3+J4)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

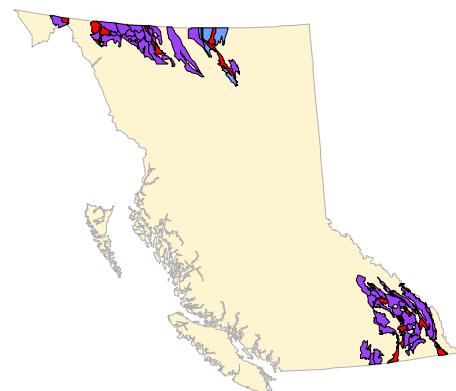

Deposit Name: Barite-Flourite Vein
Model Code: (I11/J9+J10)

50% Confidence of One Deposit in:

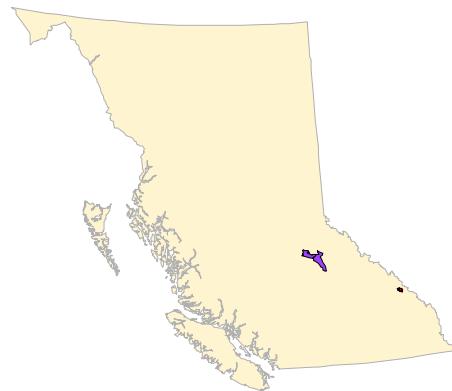

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Fluorite Vein
(Eaglet)
Model Code: (I11?/Q10)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Unconf. U-Au-Ni
Model Code: (I17/J6)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Alk. Flourite
Model Code: (I?/ALK_FLU)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Fluorite
Model Code: (I?/Flourit)

50% Confidence of One Deposit in:

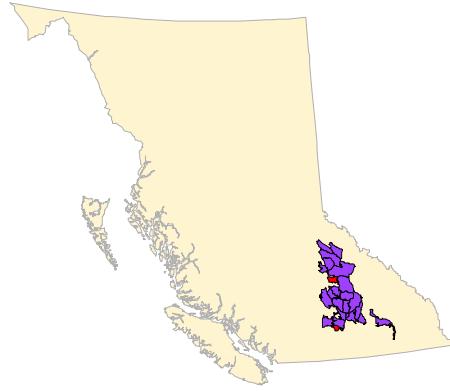

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Polymetallic Manto Ag-Pb-Zn
Model Code: (J01/M2)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Mn Veins & Replace
Model Code: (J03/K1)

50% Confidence of One Deposit in:

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Sulphide Manto Au
Model Code: (J04/M1)

50% Confidence of One Deposit in:

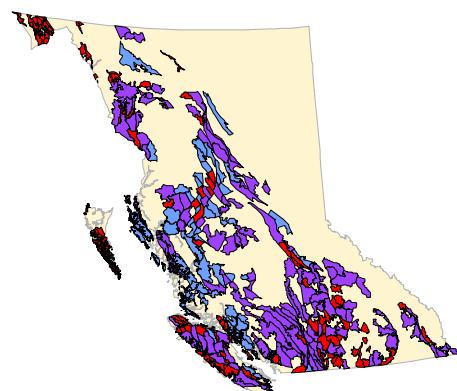

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
- █ >1,000,000 Ha

Deposit Name: Cu Skarn
Model Code: (K01/N1)

50% Confidence of One Deposit in:

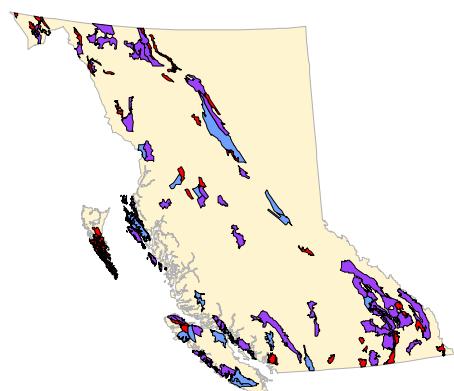

- █ <100,000 Ha
- █ 100,000 - 1,000,000 Ha
