TILL GEOCHEMISTRY OF THE CHILANKO FORKS, CHEZACUT, CLUSKO RIVER, AND TOIL MOUNTAIN AREAS (NTS 93C/1, 8, 9 & 16)

By Ray Lett¹, Stephen Cook², and Victor Levson³

KEYWORDS: till geochemistry, drift prospecting, mineral exploration, Anahim Lake, Nechako Plateau

INTRODUCTION

Till geochemical surveys applied to mineral exploration rely on detecting fragments of mineralized bedrock and/or heavy minerals as part of dispersal trains in glacially transported sediments. Surveys carried out previously in the Nechako Plateau (*e.g.* Levson, 2002) have clearly demonstrated that precious and base metal mineralization can be found in central BC using drift prospecting. This report presents unpublished till geochemical data from surveys carried out in the eastern part of the Anahim lake map sheet (NTS 93C). The surveys were conducted in 1992 as part of a BC Geological Survey Interior Plateau project funded by the Canada - British Columbia Mineral Development Agreement (1991-1995). During surficial mapping of four 1:50 000 scale map areas (NTS 93C/1, 8, 9 & 16) by Proudfoot and Allison (1993a, b) and Giles and Kerr (1993a, b), a total of 331 bulk till and colluviated till samples were collected. The samples were analyzed for elements by instrumental neutron activation (INAA), aqua regia digestion – inductively coupled plasma emission spectroscopy (aqua regia/ICP-ES) and lithium metaborate fusion - ICP-ES. Due to a lack of resources, the geochemical results of these surveys were not published. Recent interest in the Nechako plateaus has provided the impetus to compile and release this data. The location of the four map areas, covering an estimated 3600 km², is shown in Figure 1.

PHYSIOGRAPHY

The study area occurs entirely within the Fraser Plateau, in the west-central part of the Interior Plateau (Holland, 1976). In the study area, the plateau is approximately 1100 to 1400 m above sea level and is dissected by rivers such as the Tatla Lake, Chilanko, Clisbako, Chilcotin, Clusko and Baezaeko rivers which drain easterly through the region. The plateau has flat to gently rolling topography broken by occasional ridges or mountains rising up to elevations of about 1700 m. The undulating landscape and scattered mountains (*e.g.* Arc, Toil and Thunder Mountains) are typical of BC's Interior Plateau. Locally features such as hummocky moraine, flutings, dumlins and eskers reflect the effects of Pleistocene glaciation in the area.

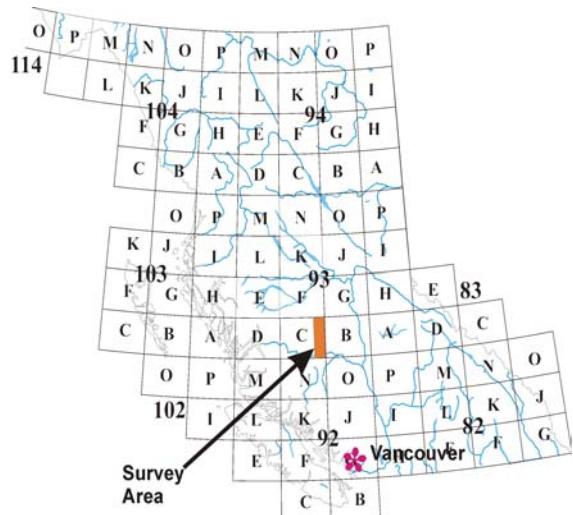

Figure 1. Location of the till geochemistry survey area. The Chilanko Forks (93C/1), Chezacut (93C/8), Clusko River (93C/9) and Toil Mountain (93C/16) map sheets are indicated by the shaded region.

BEDROCK AND ECONOMIC GEOLOGY

The bedrock geology of the survey area is summarized in Figure 2. The oldest rocks are andesite, basalt, tuff and breccia of the mid Jurassic Hazelton Group. These rocks outcrop mainly in the southern part

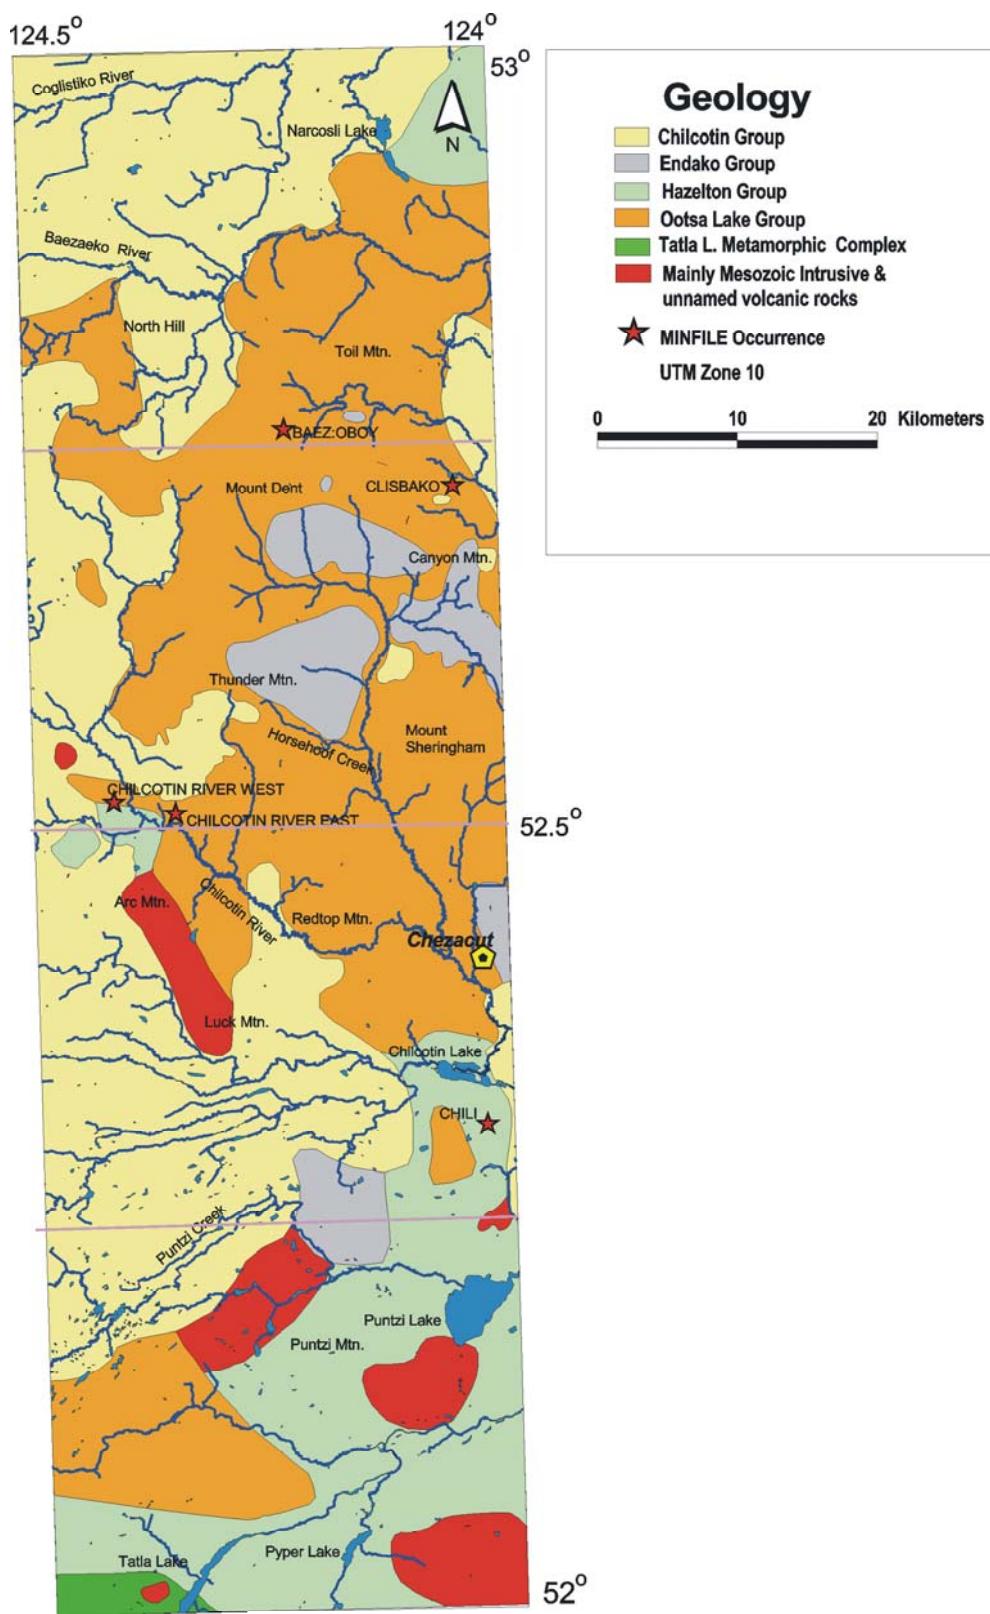

Figure 2. Geology of the survey area (by aqua regia-ICP). Key topographic features in the region are identified on the map.

of the survey area and are intruded by grandiorite and granite of the Coast plutonic suite. Covering much of the area are Eocene and Miocene volcanic rocks. Metcalfe and Hickson (1995) separated the Eocene Clisbako volcanics into four lithological assemblages comprising 1) plagioclase-augite dacite flows, 2) biotite-bearing rhyolite flows and flow breccias, 3) quartz porphyry bodies and 4) amygdaloidal lavas. The youngest rocks in the area are Miocene Chilcotin Group basalt flows that fill the river valleys. Metcalfe and Hickson (1995) suggested the Eocene volcanic rocks originated from a pyroclastic eruption in a large (50 km diameter) caldera centered approximately on Clisbako Lake.

There are presently five documented mineral prospects in the survey area. All have been classified as epithermal Au-Ag low sulphur deposits or have the characteristics of this style of mineralization.

The following descriptions have been provided by the MINIFILE database.

Chili or Punt Showing (MINFILE 93C/11): This showing is underlain by the Hazelton Group, which has been largely covered by Lower Tertiary volcanic rocks of the Ootsa Lake Group, Miocene plateau basalt and Pleistocene glacial sediments. Intruding the Hazelton Group are several complexes of diorite, granodiorite and migmatitic rocks. The showing is underlain by mafic to intermediate autobrecciated and nonbrecciated hornblende-pyroxene Hazelton Group lavas that have been intruded by feldspar and quartz-feldspar porphyry dikes. The volcanic rocks comprise an unaltered phase, an epidotized phase and a quartz-altered phase that has chalcedonic quartz stringers associated with shear zones. The shear zones strike between 50 and 100 degrees with an 80 degree north to vertical dip.

Mineralization consists of argentiferous and auriferous chalcopyrite in low temperature banded quartz veins and the chalcedonic stringers. Secondary malachite and azurite are also present in these quartz veins. Minor pyrite and chalcopyrite occur within the porphyry dikes. Gold-Ag mineralization occurs in the Chili, Rose and the Birthday zones. The Chili zone is a northeast trending set of quartz veins (up to 1 metre wide) and stockworks (up to 4.5 metres wide). These crosscut conglomerate, siltstone and lapilli tuffs. A sample of vuggy quartz-veined conglomerate assayed 19.1 grams per tonne Au and 574.5 grams per tonne Ag. This zone has an inferred length of about 90 metres. The northeast trending Rose zone, 140 metres long and 10 metres wide, consists of intensely silicified and quartz veined tuffs. The highest sample from subcrop was 0.96 grams per tonne Au and 24 grams per tonne Ag. The Birthday zone is about 3 kilometres southwest of the

Chili zone and projects toward it along strike. This zone consists of intensely silicified clay and potassically altered volcaniclastic and possibly sedimentary rocks.

Chilcotin River East and West (MINFILE 93C/13 & 14)

The Chilcotin River East showing is underlain by rocks of the Hazelton, Ootsa Lake and Endako Groups, and overlain by Miocene plateau basalt. Hazelton Group volcanic and related sedimentary rocks are intruded by small foliated granodiorite and diorite complexes. Younger undeformed quartz porphyry dikes cut these older rocks. At the Chilcotin River East showing Cu mineralization is hosted by Ootsa Lake intermediate to felsic volcanic and related rocks.

Baez, Oboy, Camp, Ridge (MINFILE 93C/15) The Oboy occurrence is hosted by bleached, flat-lying Lower Tertiary Ootsa Lake Group andesite flows, flow breccias and minor tuffs. The rocks are fractured in a predominant north and north-northeast direction with a minor fracture pattern striking east. The Camp zone is a broad north-northeast trending zone of pervasively bleached, pyritic, potassium feldspar flooded andesitic flows and flow breccias. Weathering and oxidation extends, on average, to a depth of 35 metres. Within the bleached area are more restricted steeply dipping zones of quartz-pyrite veining, brecciation and pervasive quartz-sericite alteration which are associated with anomalous As Ag and Au. Silicification occurs most commonly as numerous, vuggy quartz-pyrite druses. Chlorite and calcite occur as fracture-fillings. Highest metal values reported in a 2.0 metre drill core sample are 6.2 grams per tonne Ag, 0.32 grams per tonne Au and 995 ppm As.

Clisbako (MINFILE 93C/1) The Clisbako property is underlain by a well-differentiated sequence of Eocene subaerial, basaltic to rhyolitic tuffs, flows and volcanic breccias (Ootsa Lake Group equivalent). Remnants of a younger (possibly Oligocene) rhyolitic ash-flow tuff unconformably overlie the Eocene volcanics in the east-central part of the property and cover a more extensive area immediately to the south. Flat-lying, red, scoriaceous and black vesicular basaltic flows of Oligocene and Miocene age underlie a relatively broad, flat region extending north and east of the property. Extensive normal (extensional) faulting has affected the Eocene volcanics producing an array of variably tilted blocks.

There are at least three major (North, Central, South) and several weaker hydrothermally altered zones characterized by widespread bleaching and argillite alteration accompanied by a pervasive, moderate to strong stockwork of quartz veinlets and microveinlets. Extensive zones of multistage, intense veining, silicification and brecciation are developed. Very fine-

grained pyrite, marcasite and arsenopyrite locally are present in amounts up to 5 per cent. Two hot spring (tufa) deposits are also located on the property.

The Central alteration zone is 500 metres south-southeast of the North zone, and the South zone is 2000 metres south of the North zone. The North and South zones have an apparent true width of 350 to 400 metres; the Central zone is at least 150 metres wide. Two smaller zones referred to as the Trail zone and Discovery zone occur along the projected strike of the South zone, approximately 400 and 1200 metres respectively, to the northeast. Two broad, weaker alteration zones occur along the projected strike of the North zone, centred approximately 1500 and 2000 metres respectively to the southwest.

Outcrop is sparse on the property and is confined to main gullies and incised drainages. Eight lithological units have been mapped. Units 1 to 6 are faulted and variably tilted Eocene volcanics which are unconformably overlain by flat-lying to gently dipping, rhyolitic ash-flow tuffs (unit 8) with a local basal, densely welded, dacitic tuff member (unit 7). Unit 8 overlies lacustrine-type sediments (unit 6). Unit 1 consists of platy, light to medium green, fine-grained andesitic tuffs. The unit appears to be the main host in the Discovery zone, Trail zone, South zone and possibly the North zone. Unit 2 consists of interbedded dark grey dacitic tuff, green andesitic tuff and laminated maroon/purple/green tuff and/or tuffaceous siltstone. Unit 3 is a white to grey, dense, rhyolitic ash-flow tuff with a very finely laminated siliceous matrix; the unit is the principal host in the Central zone. Intensely altered varieties of this unit may also be present in the North zone. Unit 4 comprises medium to dark green, fine-grained, andesitic to basaltic flows. Unit 5 is basaltic in composition, fine grained, dark grey-green flow unit, which may be a member of Unit 4. Unit 6 consists of grey to brown mudstone/siltstone with abundant carbonized plant fossils and appears to be overlain by flat-lying ash-flow tuffs of unit 8. Unit 7 comprises grey, dacitic tuff and is interpreted to be a tightly welded basal member of unit 8. Unit 8 is interpreted to unconformably overlie units 1 to 5 and consists of flat-lying, white to cream-coloured, platy felsic crystal tuffs.

The alteration zones appear to have developed along complex, steeply dipping, north to northeast trending fault structures and many appear to be controlled by a series of closely-spaced, subparallel faults rather than a single major structure. The main alteration zones appear to have a long history of development, characterized by episodic periods of strong, resurgent, hydrothermal activity which resulted in several stages of fracturing, brecciation, veining and silicification.

Some phases of quartz veining and silicification are sulphide-poor while others are sulphide-rich. Pyrite is the main sulphide present, but generally is extremely fine grained and difficult to recognize. Marcasite,

arsenopyrite and pyrargyrite have also been identified. In general, better Au-Ag values occur in quartz veins which show some banding or in silicified sections which display several stages of brecciation. Carbonate minerals are rare, but coarse bladed carbonate replaced by quartz has been noted in a number of locations. In most zones, argillic alteration accompanied veining and silicification but as silicification advanced, previously argillic altered units became silicified. In the North zone, rock geochemical values average more than 0.3 grams per tonne Au ranging to a high of 1.07 grams per tonne; Ag values are in the 5 to 10 gram per tonne range. In the Central or "Ruby" zone, Ag values up to 97.7 grams per tonne have been obtained; Au assayed up to 1.09 grams per tonne. Pyrargyrite was observed in two outcrops in the Central zone" (Dawson, 1991).

SURFICIAL GEOLOGY

The surficial geology of the study area was mapped at a scale of 1:50,000 by Proudfoot and Allison (1993a, b) and Kerr and Giles (1993a, b). The dominant surficial material in the region is a silty to fine sand diamicton, interpreted as till, that forms a variable, but typically 1 to 2 m thick, blanket across much of the area (Figure 3). Surface exposures of till are up to 10 metres thick. Surface tills are typically moderately dense, massive, silty sand diamictons, locally with lenses and beds of sorted sediments. Giles and Kerr (1993) interpreted these deposits as englacial or supraglacial tills formed during glacial retreat and stagnation. Massive, dense, clay-rich diamictons, occurring in the subsurface and observed in exposures, were interpreted to be basal meltout or lodgement till deposited during ice advance. Basal tills consist dominantly of locally-derived materials whereas englacial and supraglacial tills contain relatively far-travelled debris. The scarcity of recessional moraines in the region (Figure 4) and abundance of hummocky topography suggests that widespread ice stagnation occurred. As a consequence, there are large areas where little basal till occurs at the surface and follow-up till geochemical programs will require the use of specialized techniques (Levson, 2001).

Glaciofluvial outwash and fluvial deposits are found along most river valleys and in meltwater channels (Figures 3 and 4). Well-sorted sand deposits are fairly common at the base of larger meltwater channels such as those now occupied by the Chilcotin, Chilanko and Baezaeko rivers. Terrace gravels in these valleys are typically 1 to 5 m thick deposits but attain thicknesses of 20 m in the Chilcotin River valley. Glaciofluvial deposits in the region also include isolated eskers and esker complexes. The latter are sand and gravel ridges that branch and rejoin in braided patterns with intervening kettle depressions. A particularly large esker complex in the Chilanko River valley is 8 km long, 1 km wide and up to 30 metres high. More

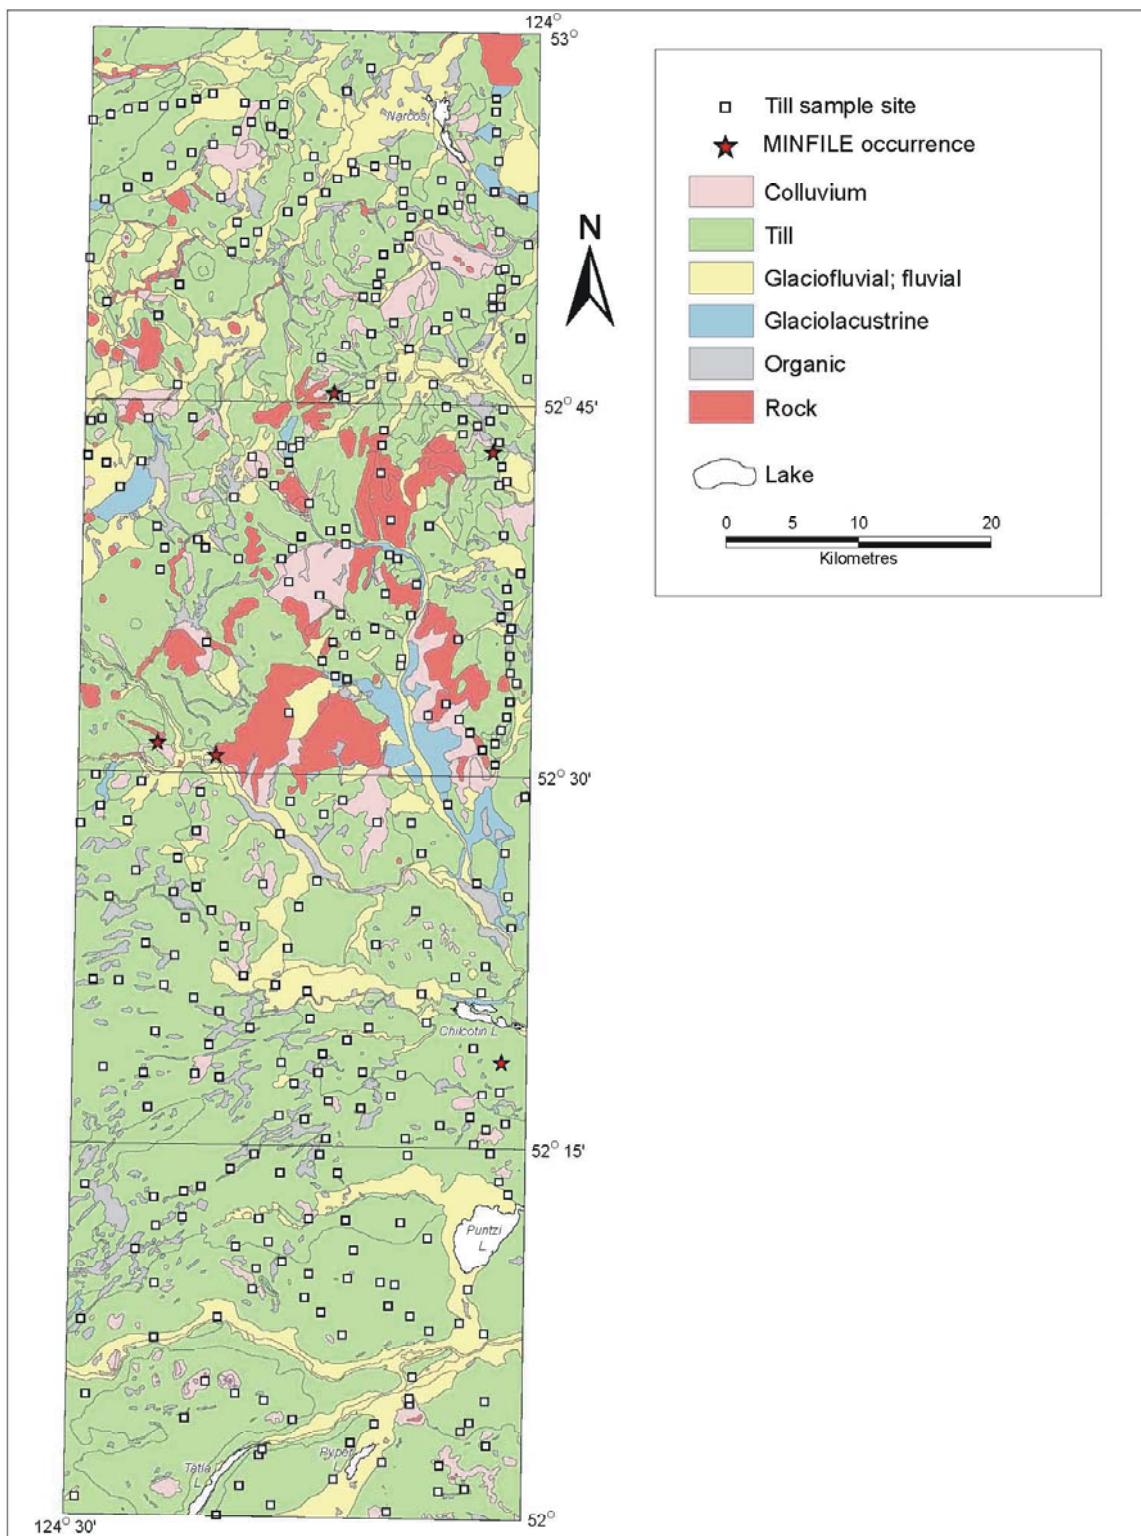

Figure 3. Surficial geology based on mapping by Proudfoot and Allison (1993a, b) and by Giles and Kerr (1993a, b).

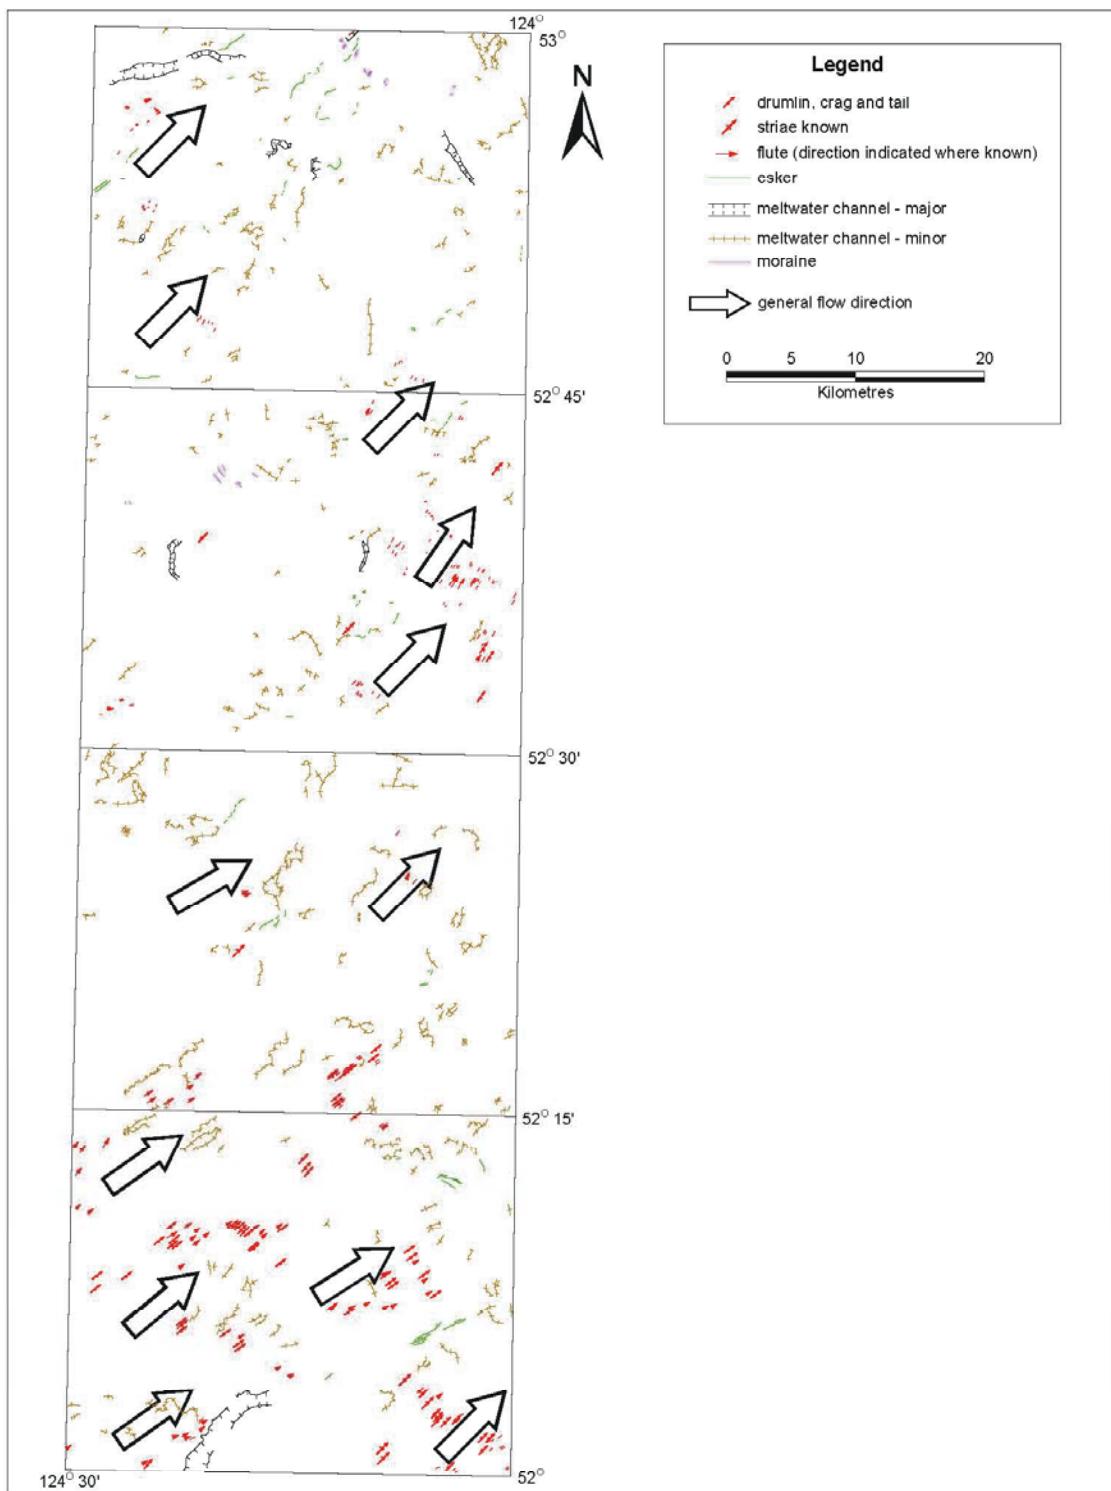

Figure 4. Surficial geology based on mapping by Proudfoot and Allison (1993a, b) and by Giles and Kerr (1993a, b).

typically, esker complexes are 50 to 400 m wide and 500 to 1500 m long, with individual ridges 5 to 15 m high (Giles and Kerr, 1993). Most eskers and esker complexes in the study area trend easterly to northeasterly (Figure 4) suggesting that late subglacial and englacial meltwater flows were topographically controlled.

Other surficial sediments in the study region include glaciolacustrine sediments, organic deposits and colluvial sediments (Figure 3). The largest area of glaciolacustrine deposits occurs along the Clusko River valley as a ubiquitous blanket of parallel-laminated sands, silts and clays up to 8 m thick (Proudfoot and Allison, 1993a, b). Relatively large areas of bedrock and colluvium occur in the Clusko River map area (NTS 93C/9) around topographic highs such as Thunder Mountain and Mount Dent (Figure 3). A loose cover of weathered and broken bedrock near the mountain tops grades downhill into a thin veneer of colluvial diamictite and till. Organic deposits are common throughout the region in low lying, poorly drained sites both on the plateau and within broad valleys and meltwater channels (Figure 3). Organic deposits consist mainly of decayed marsh vegetation with minor sand, silt and clay. Eolian sediments are relatively uncommon in the region except overlying glaciolacustrine and some glaciofluvial deposits where they occur widely as eolian veneers and low-relief, sand dunes.

QUATERNARY GEOLOGY

The oldest reported Quaternary sediments in the study area are sands and gravels unconformably overlain by 1 to 2 m of till on the upland between Tatla Lake Creek and Pyper Lake (Giles and Kerr, 1993). These coarse-grained sediments are more than 5 m thick and are interpreted as glaciofluvial outwash deposited during the advance of Late Wisconsinan glaciers in the region. Although common in other parts of the Cordillera (Clague, 1989), sediments deposited prior to the Late Wisconsinan are rarely observed in the Interior Plateau. Tipper (1971b) documented westward dispersal of erratics from the interior to the Coast Mountains that he attributed to an earlier, more extensive glaciation. However, Giles and Kerr (1993) and Proudfoot (1993) did not find evidence for any previous glaciations in the study region. Likewise, interglacial sediments underneath till are rarely observed in the region (Plouffe and Levson, 2001).

During the peak of the Fraser glaciation, the study area was entirely covered by ice that advanced northeasterly from the Coast Mountains across the Interior Plateau. A widespread cover of dense basal till was deposited at this time and numerous drumlins and flutings developed. At least one late-glacial readvance of ice from the Anahim Lake region may have reached

the westernmost edge of the study area (Tipper, 1971a). During deglaciation, large regions of the ice sheet stagnated resulting in the widespread deposition of englacial and supraglacial meltout tills at surface, especially in areas of hummocky moraine. Also during deglaciation, numerous subglacial meltwater channels, eskers and esker complexes developed under the stagnating ice. Glaciofluvial sands and gravels were also deposited as thick sequences in channels and in outwash plains in front of the ice. Glacial lakes formed locally where meltwater was dammed by stagnant ice such as in the Clusko River valley region (Giles and Kerr, 1993; Proudfoot, 1993). In the Holocene, many glaciofluvial deposits were incised and reworked by modern rivers. Organic deposits also accumulated in low lying areas during the Holocene. Colluviation has been ongoing in steep upland areas since the retreat of ice, forming thin diamictite veneers on slopes (Giles and Kerr, 1993).

ICE FLOW HISTORY

During the Late Wisconsinan Fraser glaciation, the study area was covered by ice that originated in the Coast Mountains and flowed north, northeast and east onto the Interior Plateau (Tipper, 1971b). Ice flow indicators with similar trends at many high elevation locations suggest that the ice was thick enough to flow largely undeterred by topographic features at the glacial maximum. Glaciers from the Coast Mountains extended as far east as the Fraser River before meeting ice flowing west and northwest from the Cariboo Mountains. The two ice masses coalesced and flowed generally northwards (Tipper, 1971b). More variable ice flow trends at lower elevations in the Anahim Lake region, suggest that during deglaciation, ice flow was increasingly controlled by topography as the glaciers thinned.

The orientations of drumlins, flutings and striae on bedrock (Figure 4) indicate that the dominant ice flow direction during the last glaciation was east-northeasterly (050° - 065°) in the southern part of the study area and gradually shifted to north-northeasterly (020° - 030°) in the north part (Tipper, 1971a, b; Giles and Kerr, 1993; Proudfoot, 1993). In the Chilanko Forks map area (NTS 93 C/1) large-scale flutings and drumlins indicate a flow toward the northeast (050° - 065°). Glacial striae in the southeast corner of that map sheet trend between 059° and 082° and may reflect lower elevation, topographically influenced, ice flow during the waning stages of glaciation (Giles and Kerr, 1993). In the Clusko River map area (NTS 93 C/9), Proudfoot (1993) found striae and flutings trending 020° - 025° . Few ice flow indicators have been documented in the Toil Mountain map area (NTS 93 C/16) but Proudfoot and Allison (1993b) mapped north-northeasterly trending flutings south of North Hill and northeasterly

(040°–065°) trending flutes in the northwest part of that map area.

A later readvance initially identified by Tipper (1971a, b), appears to have covered much of the Anahim Lake map area (NTS 93C) and is postulated to have reached the westernmost edge of the study area. This event, named the Anahim Lake advance, originated to the west in the Coast Mountains and flowed onto the plateau where it spread out to the north, east and southeast. It is the eastward limit of this ice, identified by Tipper (1971b) on the basis of differential ice-flow directions and pitted or kettled terrain, that is believed to have reached the study area (Giles and Kerr, 1993). This readvance apparently effected only the westernmost part of the region in the southwest corner of 93 C/9 (Figure 4) where a few easterly-trending (~080°) flutings were recognized by Proudfoot (1993). Tipper (1971a, b) also attributed a few northeast trending flutes in the northwest corner of the Toil Mountain map area (NTS 93 C/16) to the Anahim Lake readvance.

A second late glacial readvance may also have entered the Chilanko Forks map area (NTS 93C/1) through the Tatla Lake valley (Tipper, 1971a; Giles and Kerr, 1993). This Kleena-Kleene advance originated from the south and was topographically controlled as it flowed north and northeast along the Tatla Lake, Tatlayoko Lake, Kleena-Kleene and Chilko valleys. Tipper (1971a) placed the limit of this advance on the slopes along Tatla Lake Creek at an elevation of 1065 to 1220 metres.

Till sampling, preparation and analysis

Three hundred and thirty one bulk sediment samples (1–5 kg) were collected at an average density of one sample per 10.6 km². Sample locations are shown in Figure 3 and in Appendix 3. Proudfoot and Allison (1993a, b) collected the samples in 93C/9 & 16; Kerr and Giles (1993a, b) collected the samples in 93C/1 & 8. Most of the samples taken for geochemical analyses were collected from basal till which is the preferred sample medium for regional till geochemical surveys of this type (Levson, 2001). Although emphasis was placed on collecting basal till samples, ablation till, colluviated till and colluvium were also collected under certain circumstances. Natural exposures and hand excavation were used to obtain samples, including field replicates, from undisturbed, unweathered C horizon (parent material) deposits.

Till samples were air dried, split and sieved using stainless steel sieves at the British Columbia Geological Survey, Victoria laboratory. The -230 mesh (< 63

micron) fraction of each sample was analyzed for Au, As and Sb and a suite of trace and rare earth elements by instrumental neutron activation analysis (INAA) at Activation Laboratories Ltd., Ancaster Ontario, and for Cu, Zn and other trace elements by inductively coupled plasma-atomic emission spectroscopy (ICP-ES) at ALS Chemex Labs Ltd., North Vancouver. A number of the till samples were also analysed by Acme Analytical Labs, Vancouver for eleven major element oxides and five minor elements by lithium borate (LiBO₂) fusion-ICP-ES and also for loss on ignition. One split from each sample was reserved for grain size and other additional analyses.

Neutron Activation Analysis

INAA analysis was conducted on an approximately 30 gram sample split. This analytical technique involved irradiating the sample for 30 minutes in a neutron flux of 7×10^{11} neutrons/cm²/second. After a decay period of approximately 1 week, gamma-ray emissions for the elements were measured using a gamma-ray spectrometer with a high-resolution, coaxial germanium detector. Counting time was approximately 15 minutes per sample and the results were compiled on a computer and converted to concentrations. The elements and their stated detection limits are listed in Table 1.

Acid Digestion – Inductively Coupled Plasma Emission Spectroscopy

All elements except mercury were determined by inductively-coupled plasma-atomic emission spectroscopy (ICP-ES). A 1.0 g sample was digested with concentrated nitric and aqua regia acids for two hours at medium heat, diluted to 25 ml with distilled water, mixed and analyzed using a Jarrell Ash 1100 plasma spectrometer. Analytical results were corrected for spectral interferences. Unlike INAA, this partial acid digestion will not completely dissolve many of the elements reported here, including Al, Ba, Be, Ca, Cr, K, Mg, Na, Sc, Sr and Ti. Mercury was determined by cold vapour atomic absorption spectroscopy (AAS). A 1.0 g sample was digested with concentrated nitric-aqua regia acids for two hours, diluted to volume, and homogenized. An aliquot of the solution was transferred to a reaction flask connected to an absorption cell. Stannous chloride was added to reduce the Hg prior to measurement by cold vapour-AAS. Detection limits for elements are listed in Table 1.

Lithium metaborate fusion – Inductively Coupled Plasma Emission Spectroscopy

A total of 249 till samples were analysed for major element oxides and minor elements. This number

Table 1. reflects those samples where there was sufficient material for all of the analyses. A 0.2 g sample of the - 230 mesh fraction was fused with lithium borate, the residue dissolved in HNO_3 and the solution analysed for SiO_2 , Al_2O_3 , MgO , CaO , Na_2O , K_2O , TiO_2 , P_2O_5 , MnO , Cr_2O_3 , Ba , Sr , Zr , Y , Nb . Samples were also analysed for loss on ignition at 1000°C . Detection limits for oxides and minor elements are listed in Table 2. Major oxide and minor element statistics for 249 samples are listed in Table 4.

DATA PRESENTATION

This report contains geochemical data for 27 of 35 elements analyzed by INAA, and for 26 of 32 elements analyzed by ICP-ES. All of the trace element values are listed in Appendix 1. Several elements in the ICP-ES (Sb , Ga , La , Tl , U , W) and INAA (Ag , Hg , Ir , Ni , Se , Sn , Sr) analytical suites are not reported here because their natural abundance in till are lower than the stated analytical detection limits (Table 1), or because of poor analytical precision. Those concentrations below the stated detection limits are reported in the data listings as a value equivalent to, in most cases, one-half the detection limit (Appendix 1). Major oxide, minor elements and loss on ignition values are listed in Appendix 2. Distribution maps for element concentrations determined by INAA and ICP-ES are presented in Appendix 3.

There are several minor differences between elements reported here and those reported in a previously published till geochemistry survey over the adjacent Fawnie Creek map area (Levson et al., 1994). The ICP-ES analyses were conducted by two different analytical laboratories in the two survey years and, while substantially the same; there are slight differences in the reported element suites. Mercury, As, Be, and Sc concentrations are given here, but were not reported by Levson et al. (1994). Conversely, B and Br data are not included here, but were given by Levson et al. (1994). The stated ICP-ES detection limits for several elements (Ag , Ba , Cd , Mn , V and Zn) also differ slightly between the two survey years. INAA data reported here were also conducted prior to those of Levson et al. (1994), and there are slight differences in stated detection limits between the two surveys for La , Th and Rb . As well, INAA Mo concentrations were not reported by Levson et al. (1994), but are included here.

QUALITY CONTROL

The ability to discriminate real geological and geochemical trends from those arising from sampling

and analytical variation is of considerable importance in the interpretation of geochemical data. Several quality control procedures were used in the laboratory analysis component of this program, including the insertion of control standards and analytical duplicates into the sample suite, and the routine re-analysis of those samples returning high gold concentrations.

The four control standards used include CANMET certified reference materials and internal standards of the Geological Survey Branch, and span a wide range of element concentrations likely to occur in till. Control standards analytical data compare favourably with accepted values. Mean values for replicate analyses of these standards and percent relative standards deviation (%RSD) values are listed in Table 1. For example, four INAA analyses of CANMET standard STSD-1 returned mean concentrations of $22.3 \text{ ppm} \pm 1.0 \text{ ppm}$ As (accepted value: $23 \text{ ppm} \pm 2 \text{ ppm}$), $3.3 \text{ ppm} \text{ Sb} \pm 0.1 \text{ ppm}$ (accepted value: $3.3 \text{ ppm} \pm 0.3 \text{ ppm}$). Four aqua regia ICP-ES analyses of the same standard returned mean concentrations of $34 \text{ ppm} \pm 4 \text{ ppm}$ Cu (accepted value: $36 \text{ ppm} \pm 2 \text{ ppm}$), $156 \text{ ppm} \pm 9 \text{ ppm}$ Zn (accepted value: $165 \text{ ppm} \pm 8 \text{ ppm}$) and $20.0 \text{ ppm} \pm 4.3 \text{ ppm}$ As (accepted value: $17 \text{ ppm} \pm 5 \text{ ppm}$). Accepted values for CANMET standards are from Lynch (1990). Four analyses of one of the high-Au internal standards returned a mean Au concentration of $220 \text{ ppb} \pm 8 \text{ ppb}$, similar to the accepted value of 250 ppb .

Analytical precision may be assessed by repeated analysis of a control standard. For example, replicate INAA analyses of each of four standards returned relative standard deviations (RSD) of 4.3 - 12.3 % for As 4.9-9.2 % for Fe, 2.9-15.7 % for Ce and 1.0-19.6 % for Ba. Gold RSD values for three of the standards are in the range of 40 %. The large RSD values for Au in SDST 3 can be explained by an erratically high (17 ppb) value for one repeat analysis of this standard. In the ICP-ES suite, four to seven replicate analyses of each of the four standards returned RSD values in the range of 3.0-11.5 % for Cu, 0.5-7.0 % for Zn, 3.6-14.2 % for Cr and 0.0-27.0 % for Hg.

Analytical duplicates are sample splits taken after laboratory preparation procedures, but prior to analysis. Figure 5 shows scatter plots generated from data for 18 duplicate sample pairs for Au, As, Ce and Fe by INAA and for Cu, Zn, Ni and Cr by ICP-ES. Results indicate good reproducibility for most elements, particularly those with concentrations well above the stated detection limits. Analytical precision is generally lower for elements such as Au, Ag, Pb and As where background concentrations are often at or near the limits of analytical detection.

Table 2. Detection limits and percent relative standard deviation for 10 repeat analyses of CANMET Standards STSD 1 and STSD 3 (LIC = Lithium metaborate fusion-ICP; GR = Gravimetric analysis; SUM = Sum of oxides).

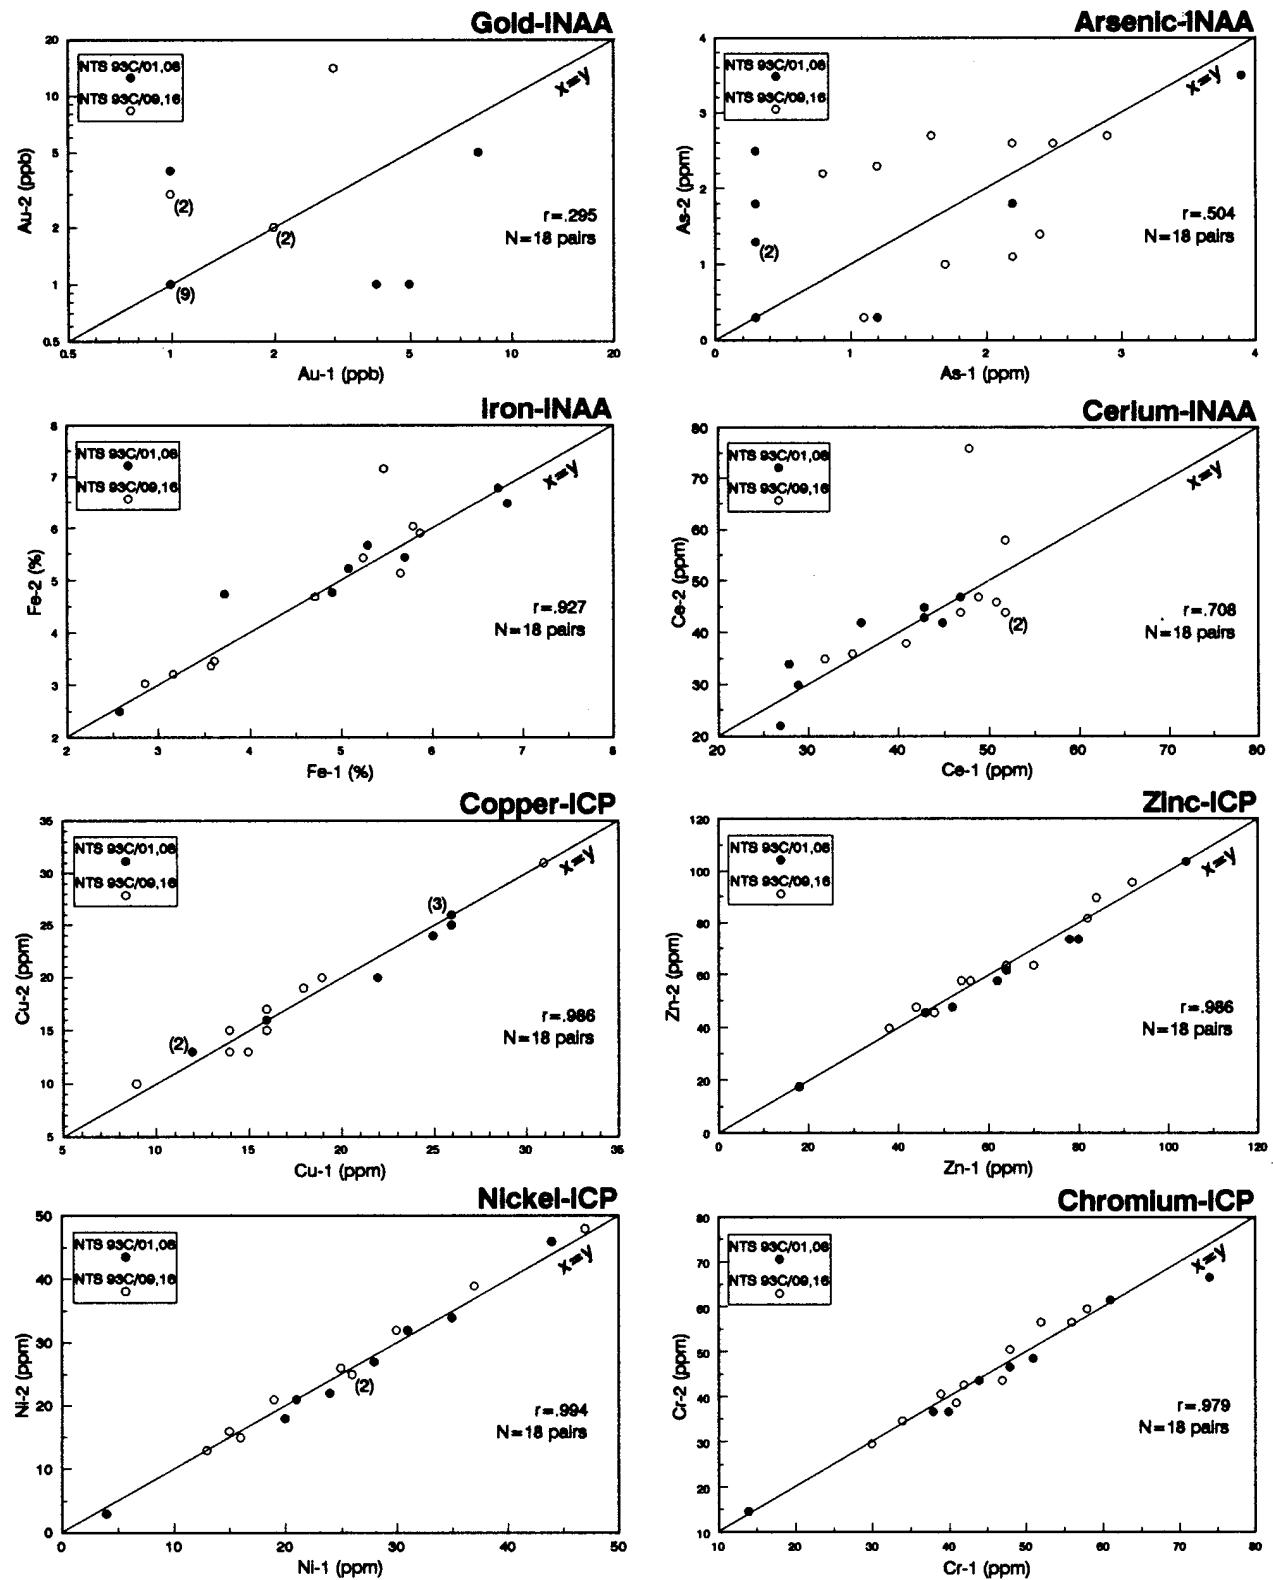

Figure 5. Scatter plots of 18 blind duplicate pairs for each of Au, As, Fe and Ce by INAA, and Cu, Zn, Ni & Cr (ICP-ES).

As a further check on analytical reproducibility of Au, repeat INAA analyses are routinely conducted on samples reporting elevated Au concentrations (i.e. >90th percentile) in each survey area. Here, repeat analyses were conducted on 21 samples from the Chilanko Forks - Chezacut area (NTS 93C/1 & 8) and 10 samples from the Clusko River - Toil Mountain area (NTS 93C/9 & 16) with Au concentrations of at least 6 ppb (Fig. 6). These correspond to the upper 14% and upper 6% of the two respective data sets. Repeat analyses are ideally conducted on separate splits of the original sieved sample material, as the results are a measure of both analytical and sub-sampling variability. Because insufficient pulp material remained available for most of these samples, the re-analyses were conducted on the original INAA sample capsules.

Results measure only analytical variability from one sample batch to another, but generally confirm the validity of the initial Au values. All of the re-analyzed samples yielded Au concentrations greater than the stated 2 ppb detection limit. More than half (17) returned Au values greater or equal to the initial 6 ppb threshold. Significantly, all 9 samples initially reporting at least 10 ppb Au also returned at least 10 ppb upon re-analysis. Six of the 31 sample repeats returned higher-than-original Au concentrations, while 3 remained the same and 22 returned slightly lower than original values. Generally, those samples containing at least 10 ppb returned repeat values of at least that level or greater, while those samples containing less than 10 ppb Au returned repeat values a few ppb lower. In all, calculated per cent difference values are 40% or better for more than half (17) of the duplicate pairs. Gold concentrations in the Appendix 1 data listings are those values obtained from the first analysis; Gold concentrations obtained from re-analyses are reported as "Au2".

Only STSD 1 and STSD 3 have been analysed for SiO₂, Al₂O₃, MgO, CaO, Na₂O, K₂O, TiO₂, P₂O₅, MnO, Cr₂O₃, Ba, Sr, Zr, Y, Nb and LOI. Precision expressed as %RSD for most oxides for both standards is generally higher than 5 percent. The exception is Cr₂O₃ and the poor precision could reflect the low levels of the oxide in the standard.

SUMMARY OF RESULTS AND PRELIMINARY INTERPRETATION

This summary of Au, As, Sb, Hg, Cu, K, Pb and Zn distributions in surficial sediment is intended to highlight geochemical patterns that could help identify exploration targets. Only raw data are used. Where

applicable, unit designations of Tipper (1969) and Metcalfe and Hickson (1995) are used to identify geological units. Most of the landscape features mentioned in this Geofile are identified on Figure 2, but readers should refer to the appropriate 1: 50 000 scale NTS topographic maps or the Cariboo Forest Region map for more local stream and place names.

In Figures 7 and 8 the distribution of till samples with anomalous Au and with As + Sb + Hg above the 90th and 95th percentiles are shown as symbol plots. The element statistics including percentiles are listed in Table 3, and have been calculated from data for the whole survey. Arsenic, Sb and Hg were chosen because these elements are pathfinders for epithermal mineralization. The geochemical summary has been separated into the Clusko-Toil Mountain area (93C/9 & 16) and the Chilanko Forks-Chezacut area (93C/1 & 8) because more detailed symbol plots showing the distribution of all elements in till samples from these two areas are contained in Appendix 3. Sample site locations and numbers are also provided in Appendix 3. Each map is accompanied by a statistical summary that has been used as a framework for describing the results.

NORTHERN HALF OF STUDY AREA - CLUSKO RIVER AND TOIL MOUNTAIN MAP AREAS

Multi-element till geochemistry (values >95th percentile) patterns in the Clusko River and Toil Mountain map sheets reveal the presence of the most important known mineral prospect in the area (Clisbako), extend the potential target area around another prospect (Obay), and indicate the potential for discovery of new, previously unknown, mineral occurrences.

Gold

Background Au concentration in tills, as expressed by the median value, is 1 ppb. There are 6 sites with Au concentrations above 6 ppb scattered over the eastern part of the survey area (Appendix 3). These sites appear primarily over Ootsa Lake Group volcanic rocks, although Au at one site (3033) is situated above a different volcanic unit of Tipper (1969). Most elevated till Au concentrations are within NTS 93C/9, but the highest Au value (32 ppb; site 4226) is located in NTS 93C/16 on the north flank of Toil Mountain, south of the Baezaeko River. The second-highest Au value (18 ppb; site 3154) is located on the north side of Clisbako Lake near the Clisbako prospect. As shown in the data listings, INAA reanalysis of the sample capsules from these sites (30 ppb and 31 ppb Au, respectively) confirms the reproducibility of these anomalous values.

Gold Repeats (INAA)

There are no distinct Au distribution patterns in till. However, two sites with elevated Au in the Clisbako area are coincident with, or adjacent to, As-Sb-Hg anomalies. Two other sites with Au values of 9-10 ppb occur near sites with elevated Cu-K concentrations in the Horsehoof Creek - Thunder Mountain area south of the Clusko River (Appendix 3).

Arsenic, Antimony and Mercury

Median As and Sb till concentrations (INAA) in the combined Clusko River-Toil Mountain survey area are 2.3 ppm and 0.5 ppm, respectively. Highest As (43 ppm) and Sb (4.6 ppm) concentrations in till occur at one site (*site 3151*) south of Clisbako Lake, near the Clisbako prospect. Median Hg concentration (AAS) in till is 30 ppb. The site with the highest Hg (*site 4228*; 470 ppb) is located north of the Clisbako River to the west of Toil Mountain. The second-highest Hg concentration (*site 3096*; 290 ppb) is west of Mount Dent near the headwaters of the Clusko River.

Overall, elevated As-Sb-Hg values (>95th percentile for each element, corresponding to concentrations greater than 6.4 ppm As, 1.5 ppm Sb and 60 ppb Hg) define two anomalous multi-element zones in till above Ootsa Lake Group volcanics. These zones, centered roughly on the Clisbako and Oboy epithermal prospects, form a discontinuous actuate belt of precious metal pathfinder anomalies along the border of the NTS 93C/9 & 16 map areas (Fig. 8). The distribution of Cs in till displays a very similar pattern. At Clisbako, the anomalous zone generally corresponds to the locations of known epithermal mineralization and argillic alteration zones (Dawson, 1991) south and northwest of Clisbako Lake. Anomalous Au values are also present at some till sites here, and the As-Sb-Hg±Au geochemical signature is similar to that present in present-day sediments of Clisbako Lake (Cook, 1995). In contrast, anomalous single- and multi-element till sites in the general region around the Oboy prospect contain less associated Au, but comprise a broad area of multi-element As-Sb-Hg anomalies. A cluster of these sites occurs in the Mount Dent region which, considering known glacial flow directions in the area, is well up-ice of the Oboy prospect. In addition one till site (*3093*; Appendix 3; Fig. 9) in the Mount Dent area has high copper. These data indicate that there is good potential for new mineral discoveries in the Mount Dent region and possibly also north and east of the Oboy prospect where a number of the multi-element anomalies occur (Fig. 8 and Appendix 3).

Copper and Potassium

Median Cu (Fig. 9) and K (Fig. 10) concentrations in till are 21 ppm and 0.09%, respectively. Sites with elevated Cu and K >95th percentile (>33 ppm and 0.18%, respectively) are clustered in two major areas: the Thunder Mountain-Horsehoof Creek area, and the Clisbako prospect area. Potassium data reported here are not total determinations, as the concentrated nitric-aqua regia acid dissolution does not completely digest silicate minerals such as potassium feldspars (Dolezal *et al.*, 1968). A tightly-clustered group of sites with mostly coincident concentrations of elevated Cu (Figure 9) and K (Figure 10) is located north of Horsehoof Creek on the southeast side of Thunder Mountain. The site with the maximum Cu concentration in the survey area (*site 3005*; 58 ppm Cu) is among these.

The zone of elevated K in till in the Thunder Mountain area is somewhat more extensive than the zone of elevated Cu. It corresponds to an area of andesite, dacite and basalt mapped as 'unit 10' by Tipper (1969), although more recent unpublished mapping by Metcalfe shows the area to be mostly dacite volcanic units with only isolated exposures of andesite. Numerous sites here have K values within the upper tenth percentile, suggesting an elevated regional K background for this area. The greatest K concentrations here occur at those sites on the immediate peripheries of the coincident Cu-K zone. For example, sites in the central part of the coincident zone contain up to 0.22% K (*i.e. sites 3005 and 3012*), whereas peripheral sites contain up to 0.52% K (*e.g. site 3074*). Elevated Au concentrations of 7-10 ppb also occur at two sites in, and down ice of, the Cu-K zone. This Cu-K ± Au geochemical signature may reflect the dispersed remnants, in till, of potassic alteration zones associated with possible buried porphyry Cu-Au mineralization in the Thunder Mountain area. Sibbick and Kerr (1995) demonstrated similar K till geochemistry (<62.5 micron fraction) to reflect the presence of the Mt. Milligan porphyry Cu-Au deposit. At this locality, north of Fort St. James in central B.C., a high-K till population (mean: 0.22% K) corresponding to the upper 8 percentiles of data reflected the location of the deposit; mean K concentration of the background population was 0.08%.

In the Clisbako region, a zone of moderately-elevated Cu concentrations up to 36 ppm, and elevated K concentrations up to 0.23% outlines known areas of epithermal mineralization and argillic alteration (Dawson, 1991) in the vicinity of the Clisbako epithermal prospect. K concentrations here are similar

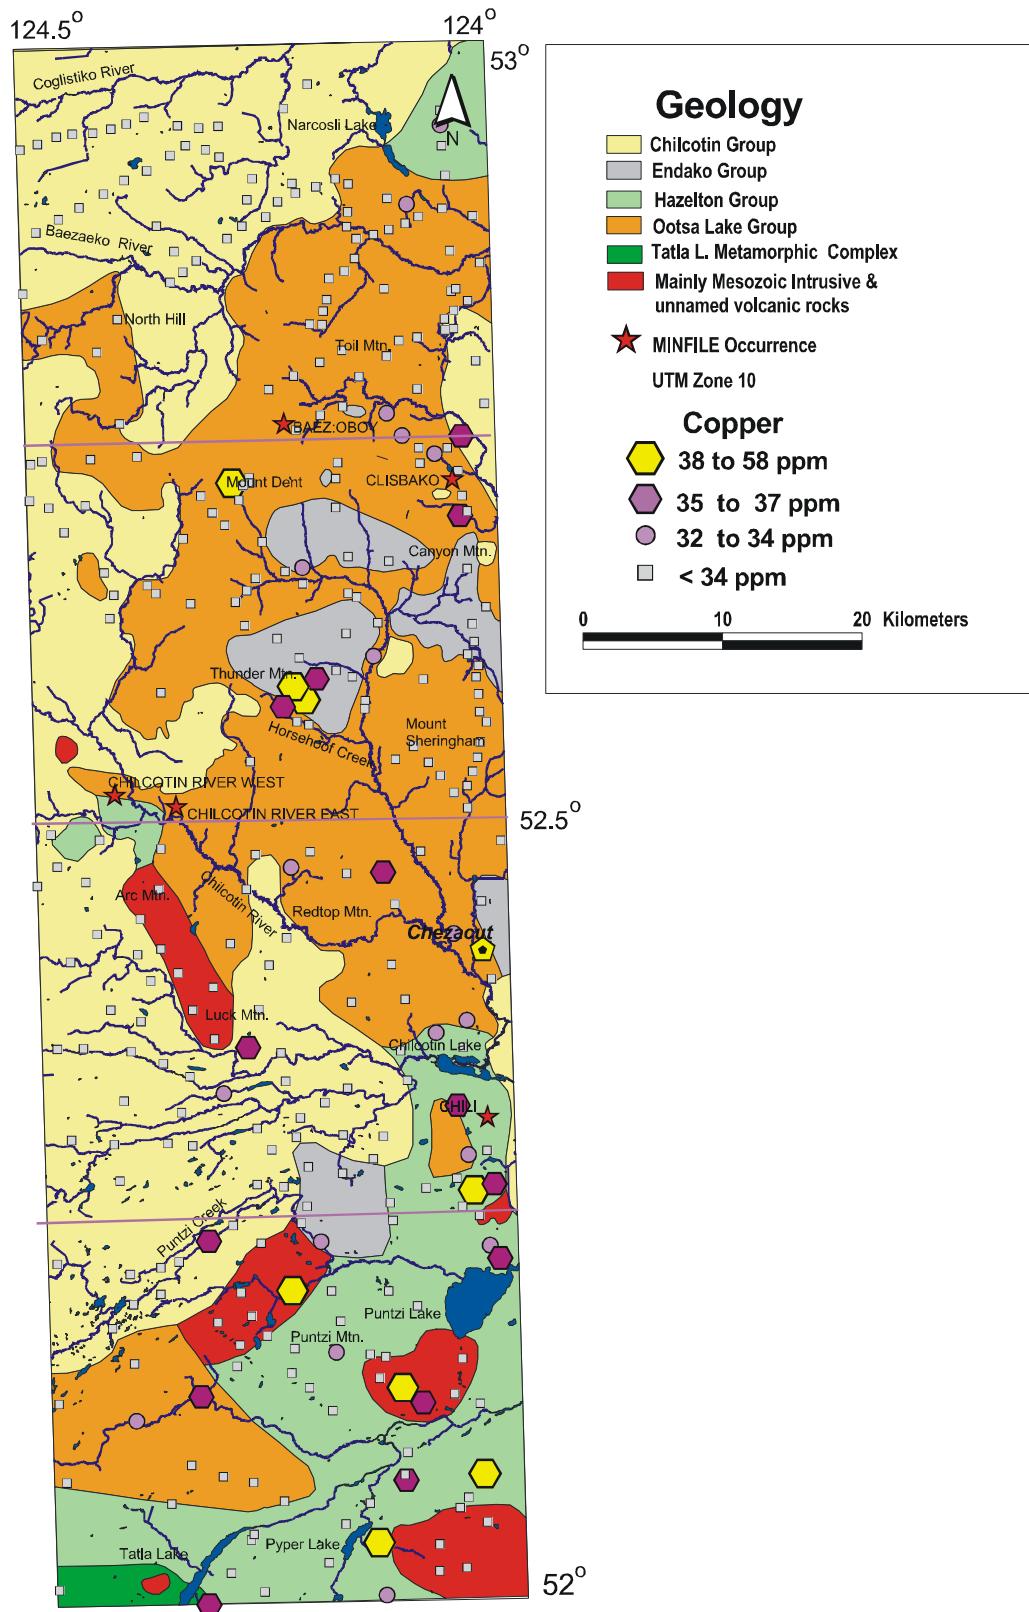

Figure 9. Copper (by aqua regia-ICP) in till.

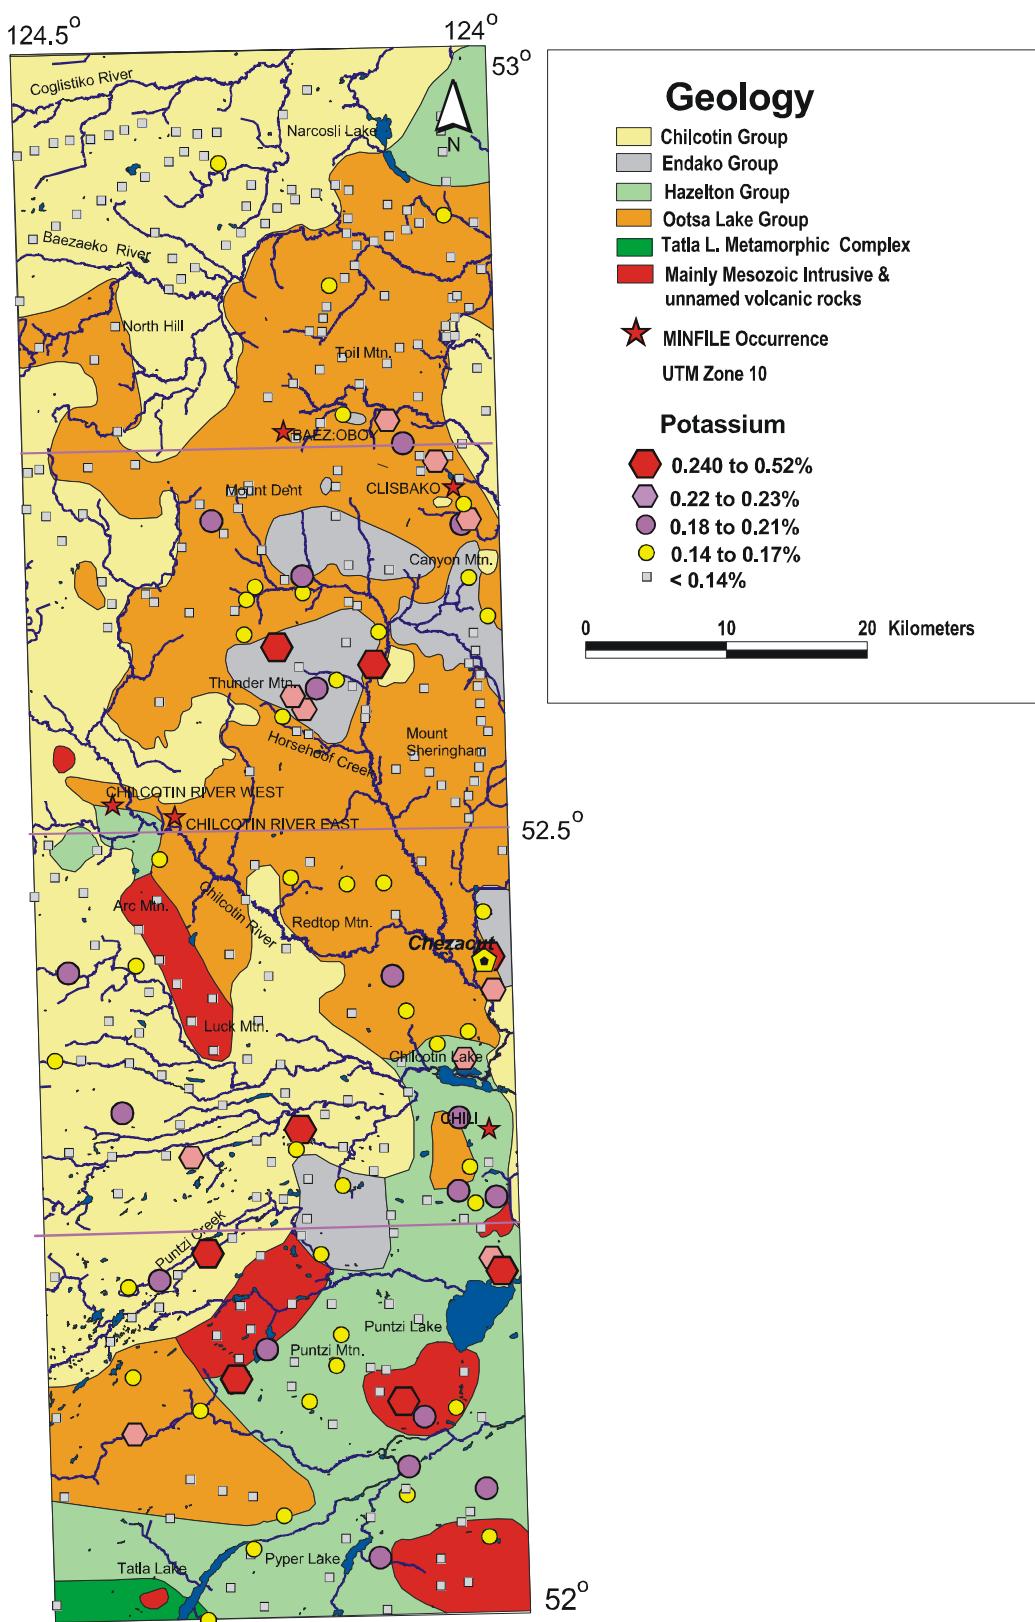

Figure 10. Potassium (by aqua regia-ICP) in till.

to those in the Horsehoof Creek-Thunder Mountain area, but Cu concentrations are lower. This area coincides with part of the previously-noted As-Sb-Hg zone. The distribution of elevated K, however, outlines a slightly larger area than do these elements, particularly to the northwest. Interestingly, there are no anomalous K concentrations in till at sites near the OBoy prospect with elevated As-Sb-Hg. In addition to the above, elevated Cu (42 ppm) is also present at site 3093 near the zone of elevated As- Sb-Hg west of Mount Dent.

Lead and Zinc

Median Pb (Fig. 11) and Zn (Fig. 12) concentrations in till are 4 ppm (max: 22 ppm) and 62 ppm (max: 162 ppm), respectively. Elevated Pb concentrations (greater than 97th percentile) of at least 14 ppm, and Zn concentrations (greater than 95th percentile) of at least 90 ppm are confined to the northern part of the survey area, in the Toil Mountain (NTS 93C/16) map sheet. There are no strong Pb or Zn patterns, but a number of sites with coincident elevated values of Pb and Zn occur in a few general areas. First, the highest Zn (162 ppm) occurs at a site (4159) just north of the Baezaeko River and two sites in the eastern Baezaeko River area (*sites 4224 and 4226; Appendix 3*) have anomalous zinc (142 and 130 ppm, respectively) and lead (14 and 14 ppm, respectively). The second highest Pb concentration in till (20 ppm) occurs at a site (4189), in the northeasternmost part of the survey area, northeast of Narcosli Lake, over Hazelton Group rocks. Secondly, two sites with elevated zinc and lead occur close together in the northwest part of the survey area, south of the Coglistiko River (*sites 4106 and 4107*), and a third anomalous site occurs about 10 km to the southwest (4119).

Summary of Northern Half of Study Area

There are several areas of interest in the Clusko River and Toil Mountain mapsheets, four of which are highlighted below.

1. Two zones of elevated As-Sb-Hg \pm Au in till in the vicinity of the Clisbako and Oboy epithermal gold prospects. Together, these two zones define a discontinuous actuate belt of multi-element precious metal pathfinder till geochemistry anomalies in the east-central part of the map area, over Ootsa Lake Group felsic volcanic rocks (Fig. 8).
2. Elevated metal values in till at the Clisbako area coincide with areas of hydrothermal alteration mapped by Dawson (1991) and with airborne gamma-ray radiometric potassium data reported by Shives (1994).

3. A zone of elevated Cu-K \pm Au values occurs above Eocene volcanic units in the Horsehoof Creek- Thunder Mountain area of NTS 93C/9.
4. In the northwest part of the survey area south of the Coglistiko River there is a small zone of adjacent and/or coincident till samples with elevated Pb-Zn values. Tills in this area of little bedrock exposure lie above what are presently mapped as basalt flows of the Chilcotin Group. A number sites with high lead and/or zinc occur at various locations in the northeastern part of the study area in the Baezaeko River – Narcosli Lake region.

SOUTHERN HALF OF STUDY AREA - CHILANKO FORKS AND CHEZACUT MAP SHEETS

There are few well-developed patterns of anomalous till geochemistry (>95th percentile) in the Chilanko Forks-Chezacut map areas relative to those in the Clusko River-Toil Mountain map areas to the north. Those patterns which are present may reflect, in part, underlying bedrock lithology, and indicate areas of potential for the discovery of new mineral prospects.

There are two sites with coincident multi-element anomalies (>95th percentile for each element) that are worthy of note: Au-As-Sb-Hg at site 2012 near Arc Mountain, and As-Sb-Hg-Cu at site 1120 near Pyper Lake in the southeast corner of the survey area. There are no elevated Mo concentrations present at any till sites in the survey area.

Gold

Background Au concentration in tills, as expressed by the median value, is 1 ppb. There are 8 sites with Au concentrations more than ~95th percentile (>8 ppb); of these, 5 sites contain at least 15 ppb Au. As shown in the data listings, INAA reanalysis of the sample capsules from these sites confirms the reproducibility of these anomalous values. There are no distinct Au distribution patterns in till of the Chilanko Forks - Chezacut survey areas. However, most sites with elevated Au values occur in the northern part of the survey area within a roughly triangular-shaped region bounded by Arc Mountain, Luck Mountain, and Redtop Mountain. This area covers a variety of rock units mapped by Tipper (1969): Jurassic rocks of the Hazelton Group, felsic volcanics of the Ootsa Lake Group, and 'unit 10' volcanics. The site with the highest Au concentration in the survey area (site 2012; 57 ppm Au), exhibiting the aforementioned Au-As-Sb-Hg till anomaly, is within this area. Several sites marginal to

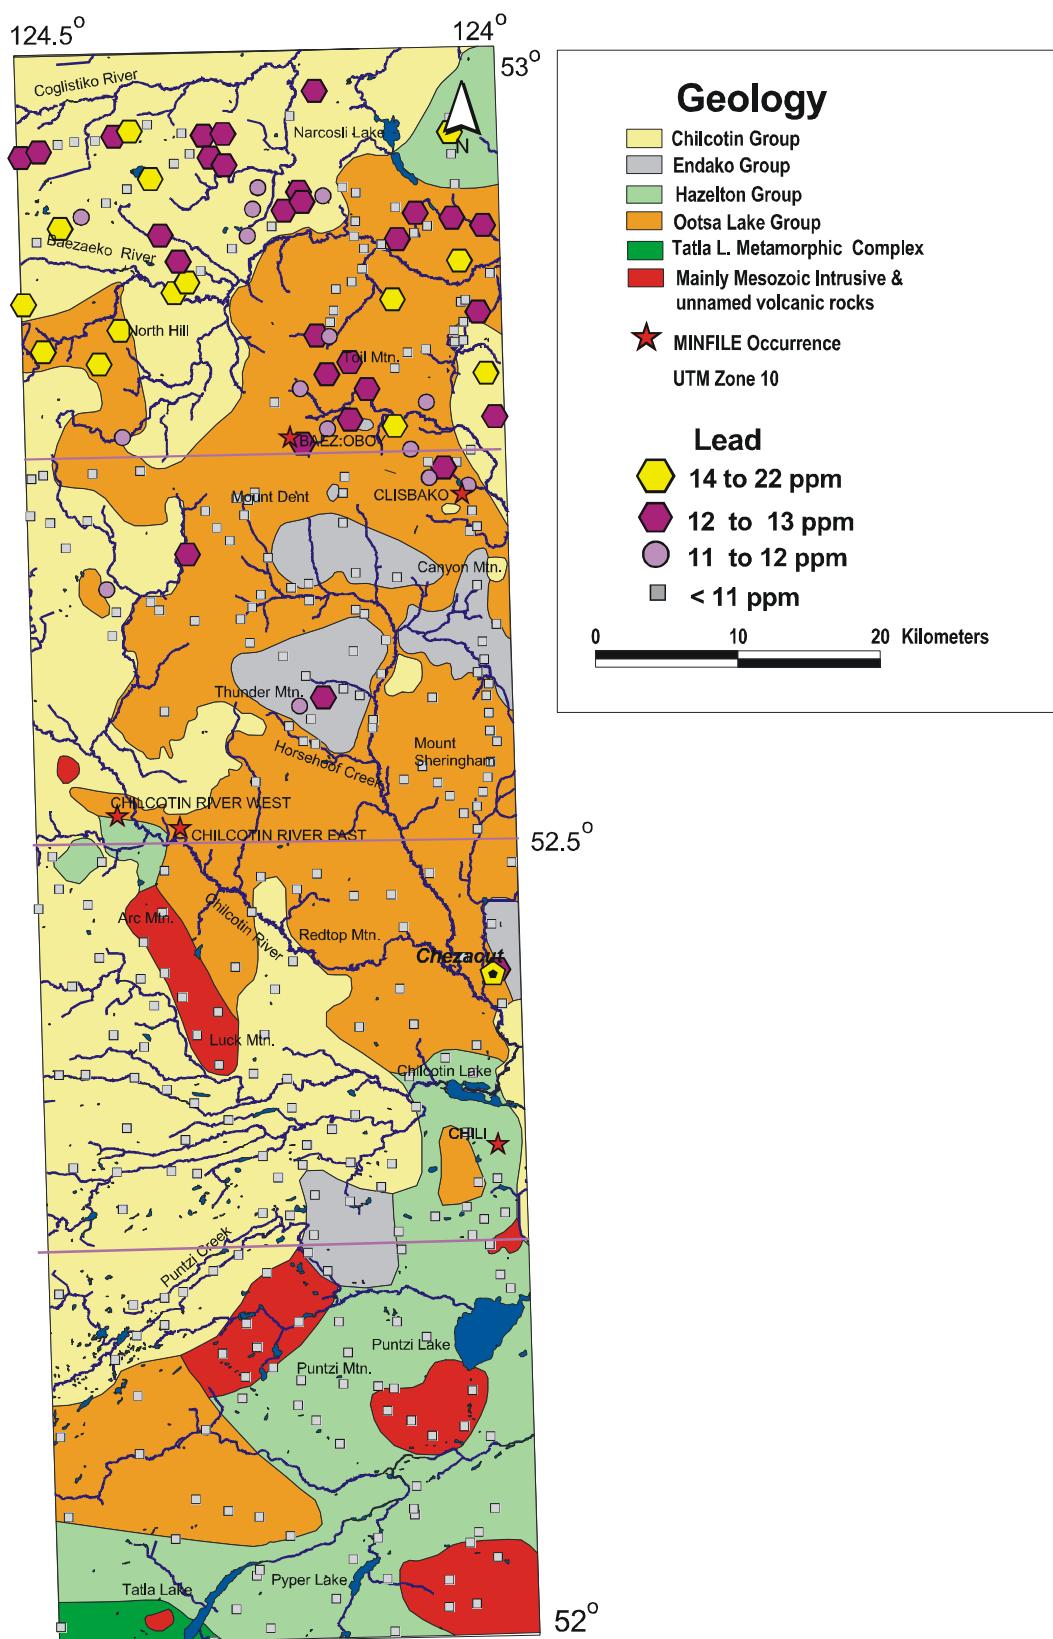

Figure 11. Lead (by aqua regia-ICP) in till.

this region, in the far northwest corner of the survey area, also exhibit elevated concentrations of some rare earth elements including cerium, europium and samarium. The second-highest Au value (site 1156; 25 ppb) is located in the southern part of the survey area between the Chilanko River and Tatla Lake.

Arsenic, Antimony and Mercury

Median As and Sb concentrations (INAA) in till in the combined Chilanko Forks-Chezacut survey area are 1.2 ppm and 0.4 ppm, respectively, slightly lower than those in the Clusko River-Toil Mountain area to the north. Highest As (25 ppm) and Sb (1.6 ppm) concentrations are found in till near the summit of Arc Mountain at site 2012, together with the highest Au value in the survey area. Median Hg concentration (AAS) in till is 20 ppb. The site with the highest Hg concentration (site 1188; 70 ppb) is located at the base of Fit Mountain in the northern part of the Chilanko Forks map area. This site coincides with the maximum Cu value in the survey area (54 ppm).

Overall, elevated As, Sb and Hg concentrations (more than ~95th percentile for each element) are lower in this area than in the Clusko River-Toil Mountain survey area to the north. Here, >95th percentile values correspond to concentrations greater than 5.9 ppm, 0.9 ppm and 40 ppm for As, Sb and Hg, respectively. Elevated concentrations of these elements are most common in the southeastern corner of the survey area on the south side of Tatla Lake Creek and Highway 20. In this area, a northeast-trending region about 20 kilometre long encompasses several till sites with somewhat elevated As-Sb ± Hg ± Cu (Appendix 3). This area is underlain by Jurassic Hazelton Group volcanics, and Jurassic gneiss, amphibolite and related rocks (Tipper, 1969).

Zinc

Elevated Zn concentrations (>95th percentile) of at least 92 ppm are confined mainly to the northeast corner of the Chezacut map area (NTS 93C/8). The highest Zn value (*site 2189*; 122 ppm) is located near the northern border of the map area a few kilometers north of the aforementioned Au-As-Sb-Hg anomaly (*site 2012*). Most elevated Zn values in till are located in the general region around Jorgensen, Knoll and Palmer creeks. Zinc concentrations in this area fall within the range of 98-114 ppm but are not coincident with elevated lead. Chromium, V, Ti, Ni, and Fe exhibit somewhat similar geochemical patterns here, suggesting a possible lithologic control on till geochemistry in this region. However, there is little geological information available

to differentiate mapped basalts (Tipper, 1969) up ice of this area, from that of adjacent areas.

Summary Southern Half of Study Area

In the Chilanko Forks – Chezacut map areas two areas of interest are defined:

1. A number scattered sites with elevated Au values in the northern part of the survey area. The most notable site in this region, at Arc Mountain, has the highest Au concentration in the survey area (*site 2012*; 57 ppb Au), as well as a coincident As-Sb-Hg till anomaly.
2. A zone of elevated Zn values in till in the region between Jorgensen, Knoll and Palmer creeks in the northwest part of the survey area.

CONCLUSIONS

Several prospective areas of interest, outlined in Figure 13, have been identified from the till geochemistry.

1. Elevated As-Sb-Hg ± Au in tills in the vicinity of the Clisbako and Oboy epithermal gold prospects, together form a discontinuous arcuate belt of anomalous samples (Area 1, Figure 13). Elevated metal values in till in the Clisbako region correspond with areas of hydrothermal alteration and with airborne gamma-ray radiometric potassium enhancement.
2. A cluster of till sites with elevated As-Sb-Hg occurs in the Mount Dent region and high copper occurs at one till site (Area 2, Fig. 13).
3. There is a zone of elevated Cu-K ± Au values above Eocene volcanic units in the Horsehoof Creek - Thunder Mountain area of NTS 93C/9 (Area 3, Fig. 13).
4. There is a small area with coincident Pb-Zn anomalies in till south of the Coglistiko River, in the northwest part of the survey area (Area 4, Fig. 13).
5. Two sites about 10 km apart, on either side of the Baezaeko River (*sites 4224 and 4226*; Appendix 3), have high zinc and lead (Area 5, Fig. 13). A third till site (4159), about 10 km to the northwest (Fig. 12), also has high lead and the highest zinc concentration in the study area.
6. The highest gold concentration in till and a coincident As-Sb-Hg till anomaly occurs at a site (2012; Appendix 3) on Arc Mountain

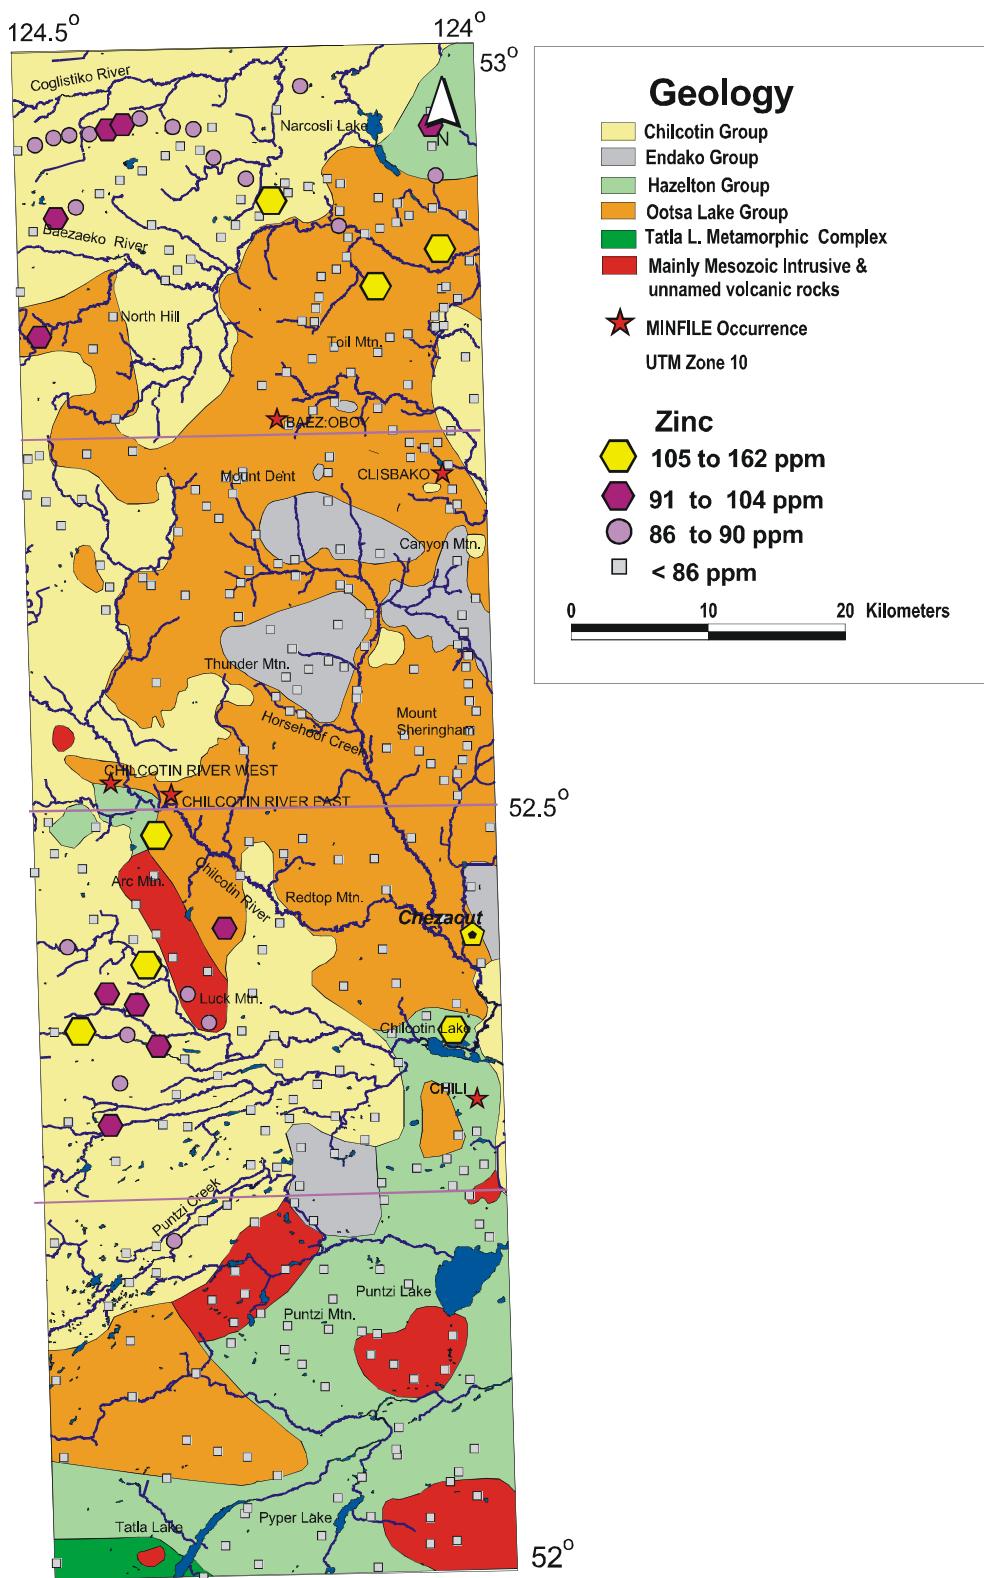

Figure 12. Zinc (by aqua regia-ICP) in till.

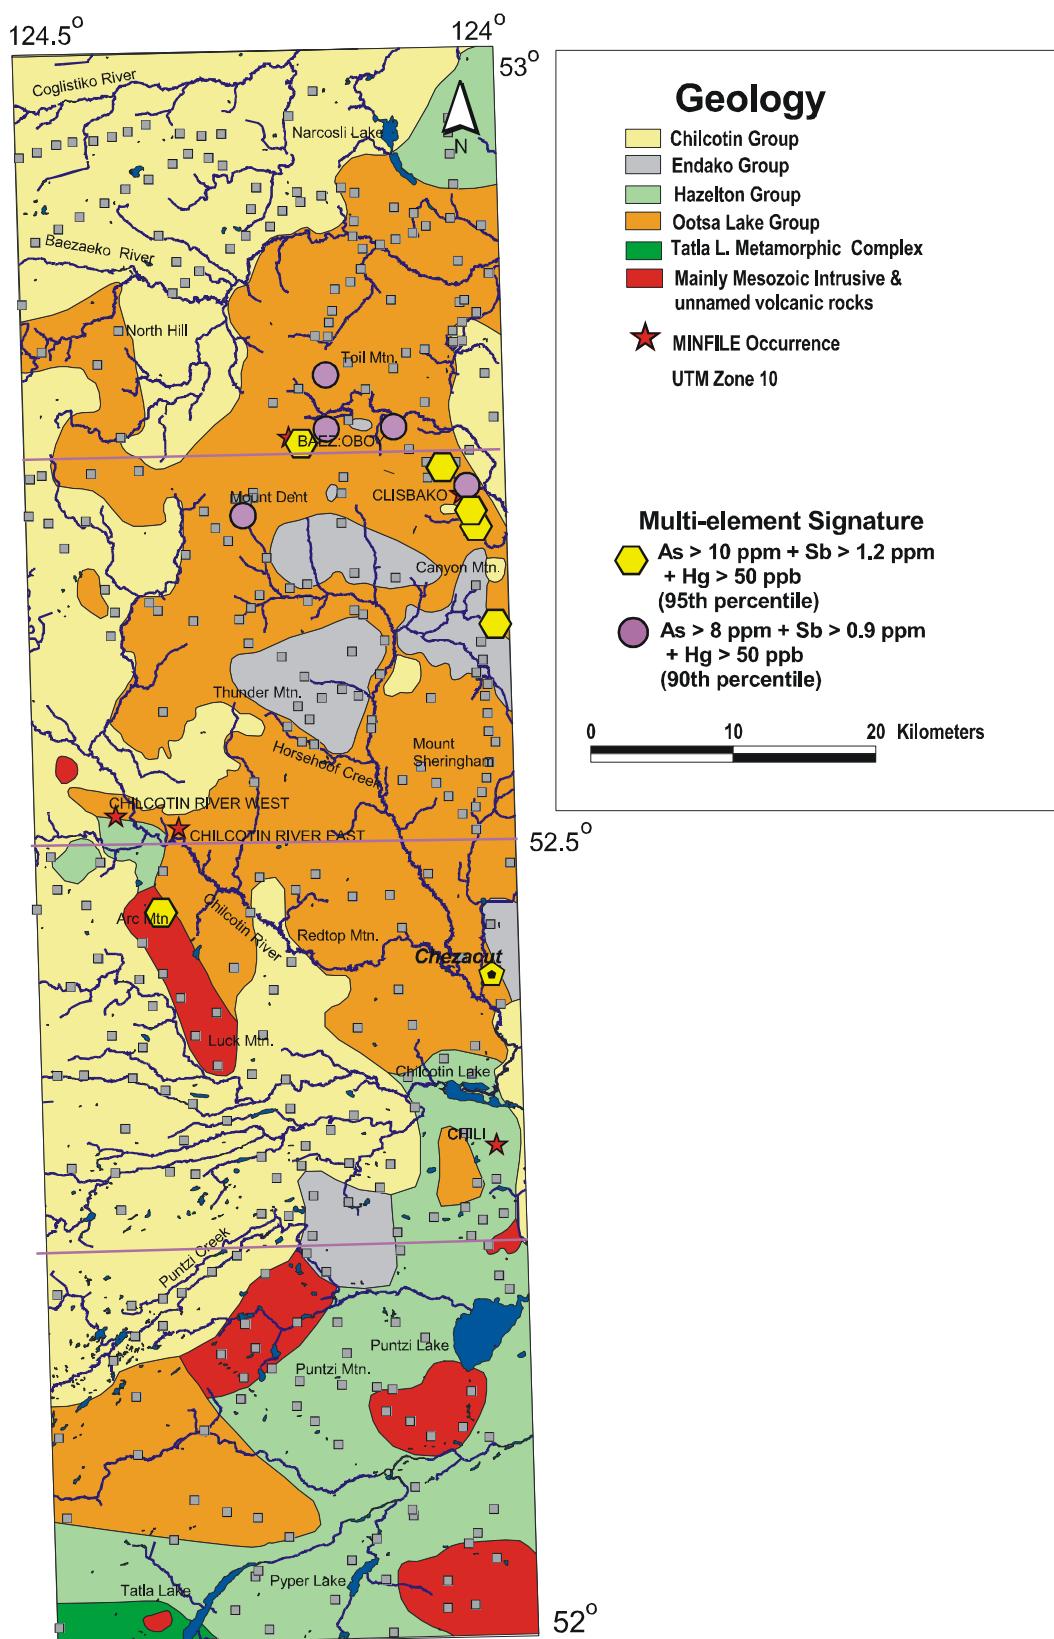

Figure 13. Anomaly summary – the numbers in or near the areas, outlined in white, refer to the conclusions.

- (Area 6, Fig. 13). Elevated gold occurs at a number of other sites in the northern part of the Chilanko Forks – Chezacut survey area (Appendix 3).
7. There is a cluster of till sites with elevated Zn values (Fig. 12) in the region between Jorgensen, Knoll and Palmer creeks (Area 7, Fig. 13).

ACKNOWLEDGEMENTS

Tim Giles and Dan Kerr collected the till samples in the Chilanko Forks and Chezacut map areas; Dave Proudfoot and Rochelle Allison carried out the sampling in the Clusko River and Toil Mountain areas. Kathy Otton prepared the till samples in the BC Geological Survey, Victoria, laboratory. Sample analyses were carried out by ALS Chemex Labs and Acme Analytical Laboratories, Vancouver, BC and by Activation Laboratories, Ancaster, Ontario. Ray Lett and Steve Cook were responsible for quality control. Northwood Geoscience Ltd., Ottawa, Ontario prepared the geochemical maps in Appendix 3. Mike Fournier structured the surficial maps in Figures 3 and 4. Paul Matysek provided management support for the project and Peter Bobrowsky managed the till geochemistry component. Nicole Robinson is especially thanked by the authors for a careful and thorough review of the Geofile text. Ryan Hinton is also greatly appreciated for editing and formatting the final report.

DEDICATION

This geochemical report is dedicated to David Proudfoot who mapped the surficial geology of the Clusko River and Toil Mountain areas as a contractor to the Ministry of Energy, Mines and Petroleum Resources (Proudfoot and Allison, 1993a, b). Dave unfortunately passed away in 1998 in the prime of his life after an outstanding professional career. Dave was a great friend and colleague of many Quaternary geologists in Canada and elsewhere. His contribution to this study is only one of many that he made to Quaternary geology in Canada. Dave contributions are recognized formally by the Canadian Quaternary Association (CANQUA) through the “DN Proudfoot Award” which is given at the national CANQUA biennial meeting.

GEOFILE 2006-1 – APPENDIX 2

Major Oxide and Minor Element Results

Sample #	Master identification number for sample.
Map #	Number specific to each 1:50 000 map sheet
Lab #	Unique GSB laboratory number
UTM Z	UTM Zone
UTM E 27	UTM East coordinate (NAD 27)
UTM N 27	UTM North coordinate (NAD 27)
UTM E 83	UTM East coordinate (NAD 83)
UTM N 83	UTM North coordinate (NAD 83)
LONG 27	Longitude (NAD 27)
LAT 27	Latitude (NAD 27)
Element ICP %	Element value with method and units. (ICP = ICP-ES, GRAV = Fusion at 1000°C).

Note: Only selected samples have been analyzed for major element oxides and minor elements because of insufficient sample availability. Samples not analyzed are represented by gaps in the data listings.

Element Oxide, Trace Element and Loss on Ignition Results

GEOFILE 2006-1 – APPENDIX 3

Element distribution maps for:

- (a) Clusko river and Toil mountain map areas in the North and;
- (b) Chilanko forks and Chezacut map areas in the South

Note: Statistics calculated for ICP-ES and INAA results for each of the two areas may differ slightly from those calculated for the whole area, and element distribution and summary statistics for major element oxides are not presented.

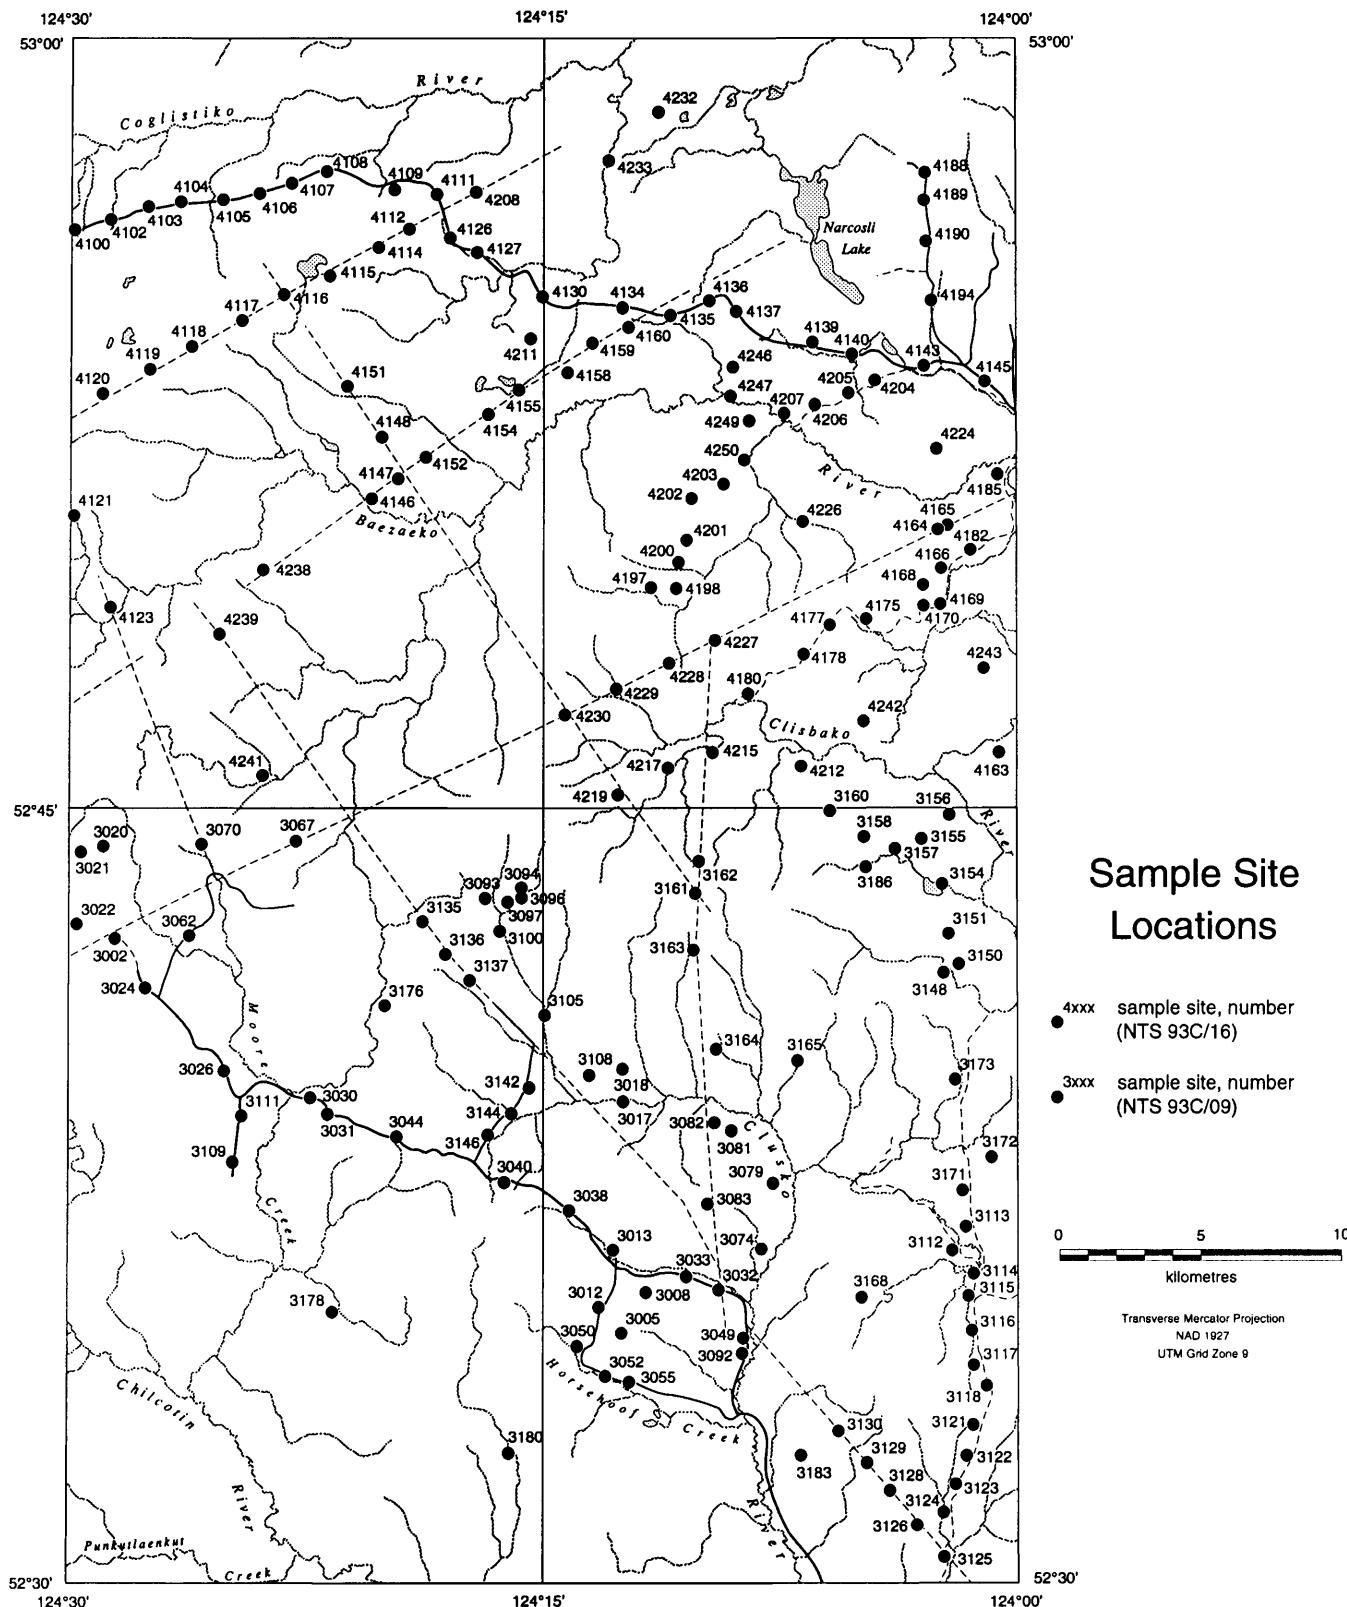

GEOFILE 2006_1 – APPENDIX 3

Element distribution maps and statistics. Note that statistics for the two areas may differ slightly from those calculated for the whole area

GEOFILE 2006_1 – CLUSKO RIVER – TOIL MOUNTAIN MAPS

Sample Locations.

Analytical Method: INA
Detection Limit: 1 ppm

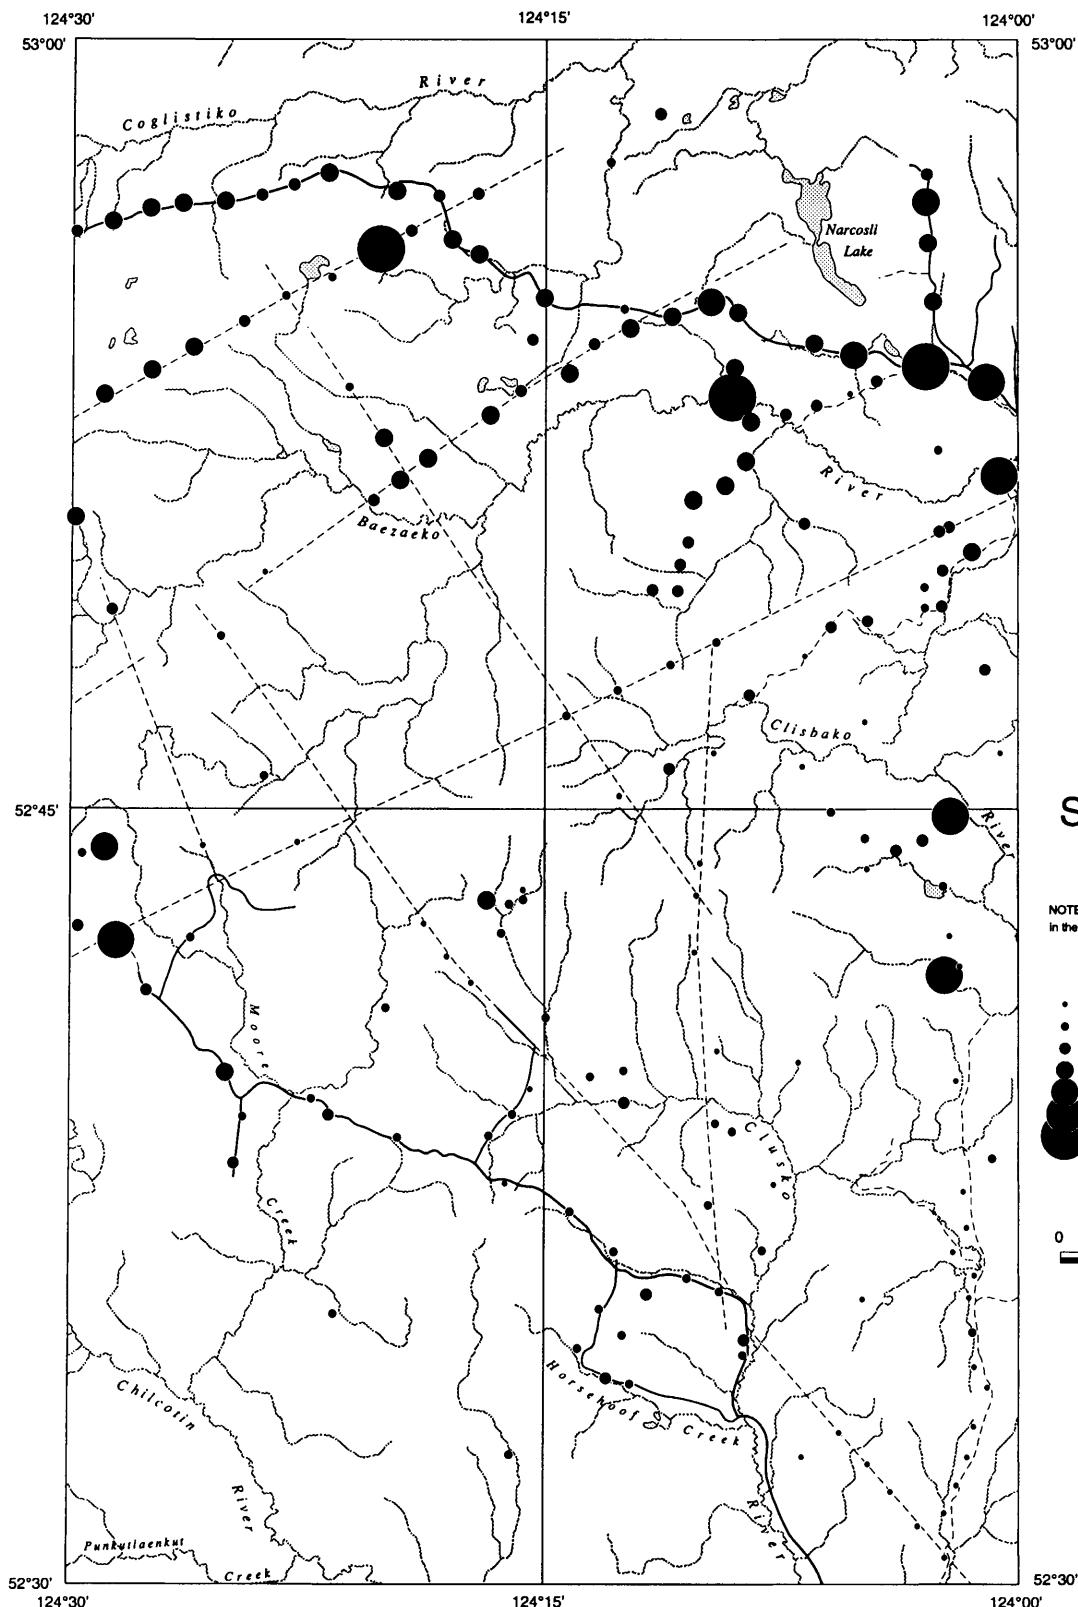

Normal Probability Curve

Summary Statistics

Number of samples: 154
Minimum: 1
Maximum: 4
Mean: 1.1
Mode: 1
Median: 1
Lower quartile: 1
Upper quartile: 1
Standard deviation: 0.4
Coefficient of variation: 2.8

Till Geochemistry of the Chilanko Forks - Chezacut Map Areas, B.C.
 NTS 93C/01 and 93C/08

Mo

Till Geochemistry of the Chilanko Forks - Chezacut Map Areas, B.C.

Sodium

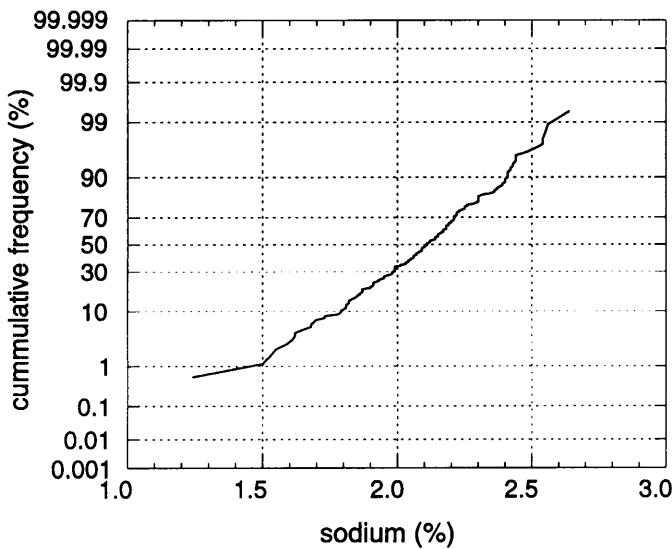

Frequency Histogram

Analytical Summary

Fraction: <0.063mm
Analytical Method: INA
Detection Limit: 0.01 %

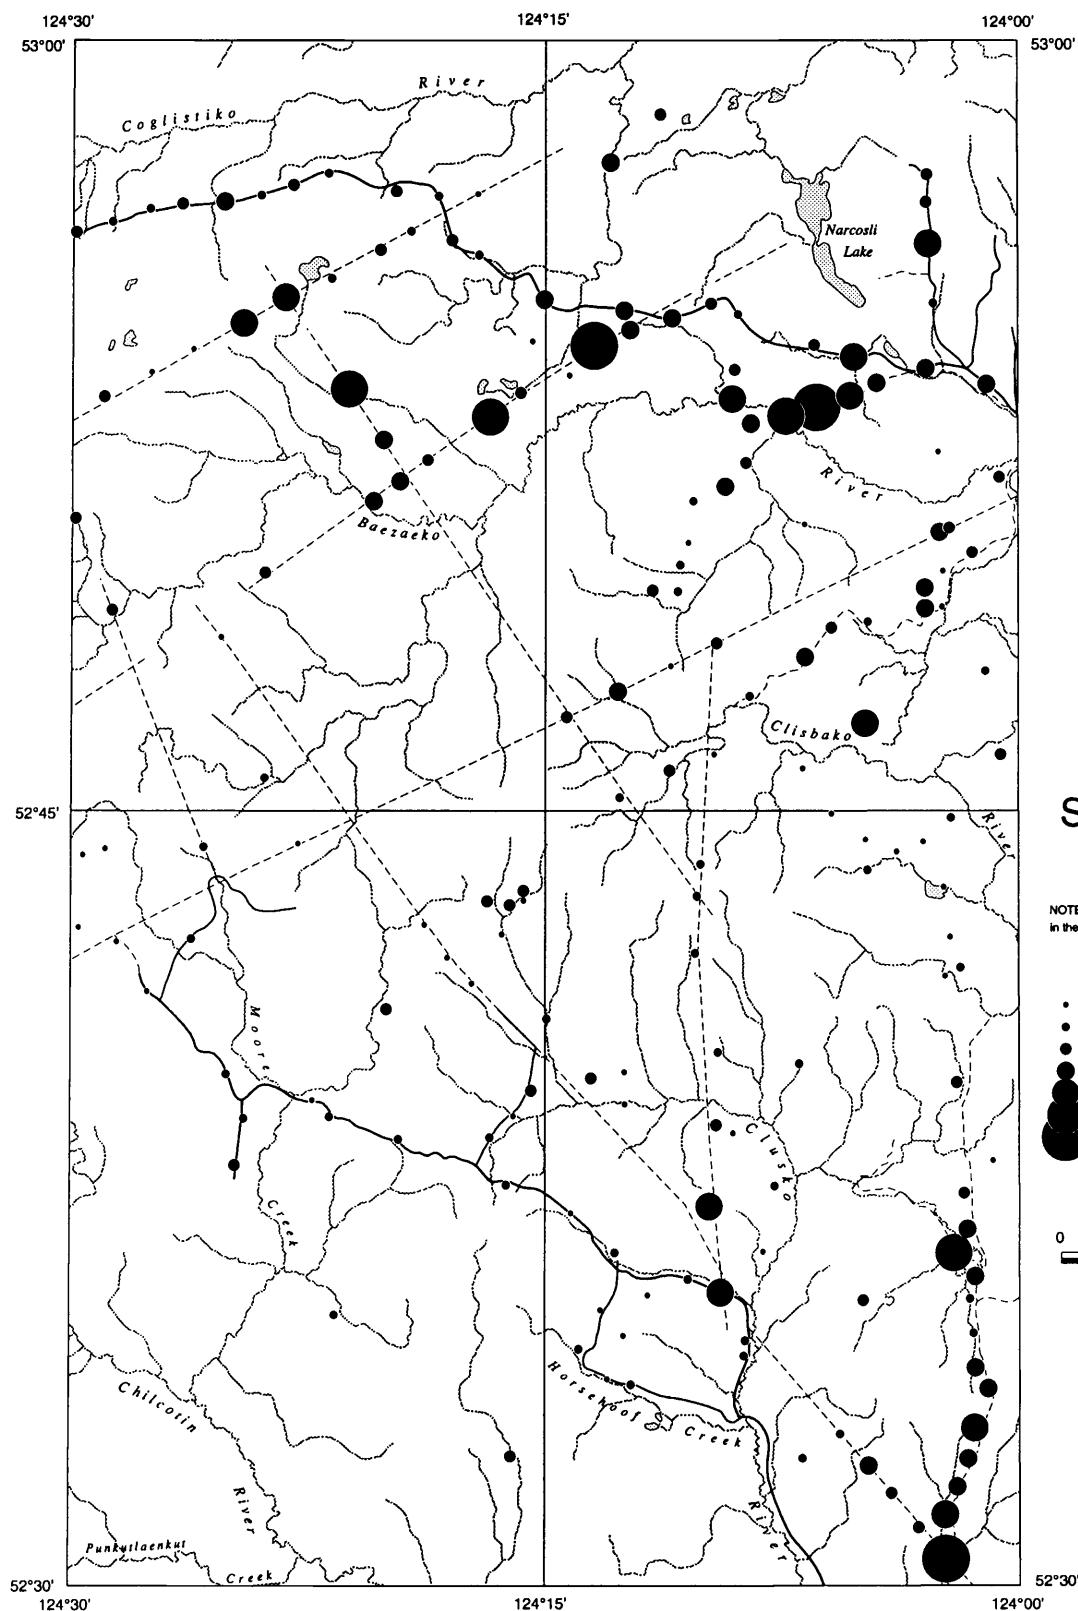

Normal Probability Curve

Summary Statistics

Number of samples: 154
Minimum: 1.43
Maximum: 3.26
Mean: 2.37
Mode: 2.36
Median: 2.36
Lower quartile: 2.22
Upper quartile: 2.51
Standard deviation: 0.24
Coefficient of variation: 13.6

Till Geochemistry of the Chilanko Forks - Chezacut Map Areas, B.C.
NTS 93C/01 and 93C/08

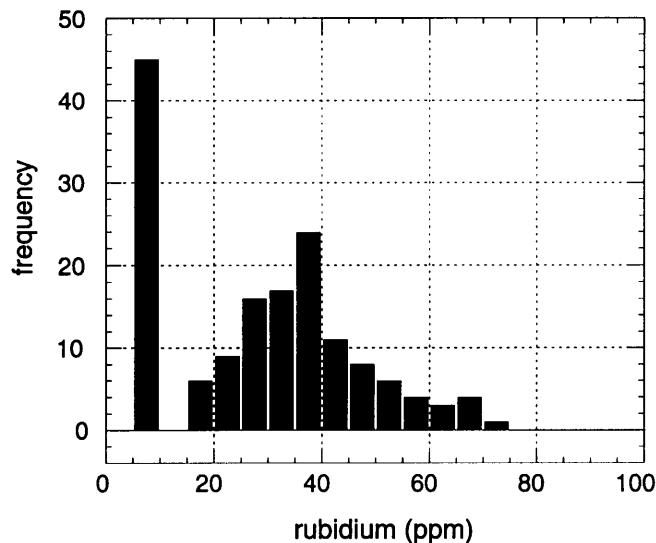

Na

Till Geochemistry of the Chilanko Forks - Chezacut Map Areas, B.C.

Rubidium

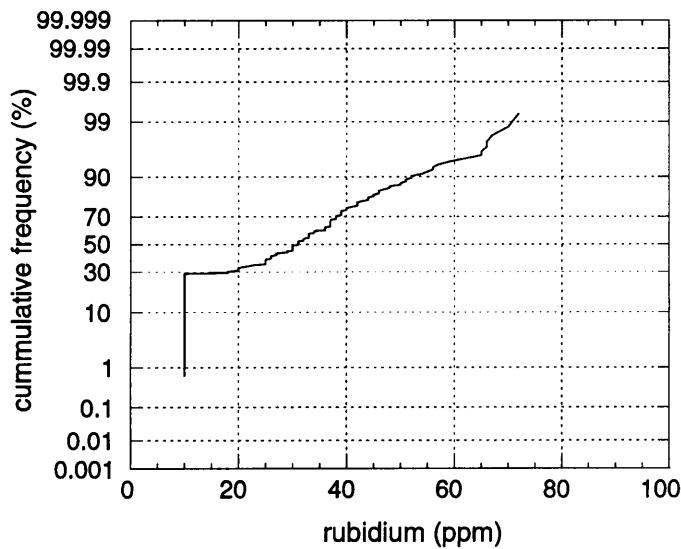

Frequency Histogram

Analytical Summary

Fraction: <0.063mm
Analytical Method: INA
Detection Limit: 15 ppm

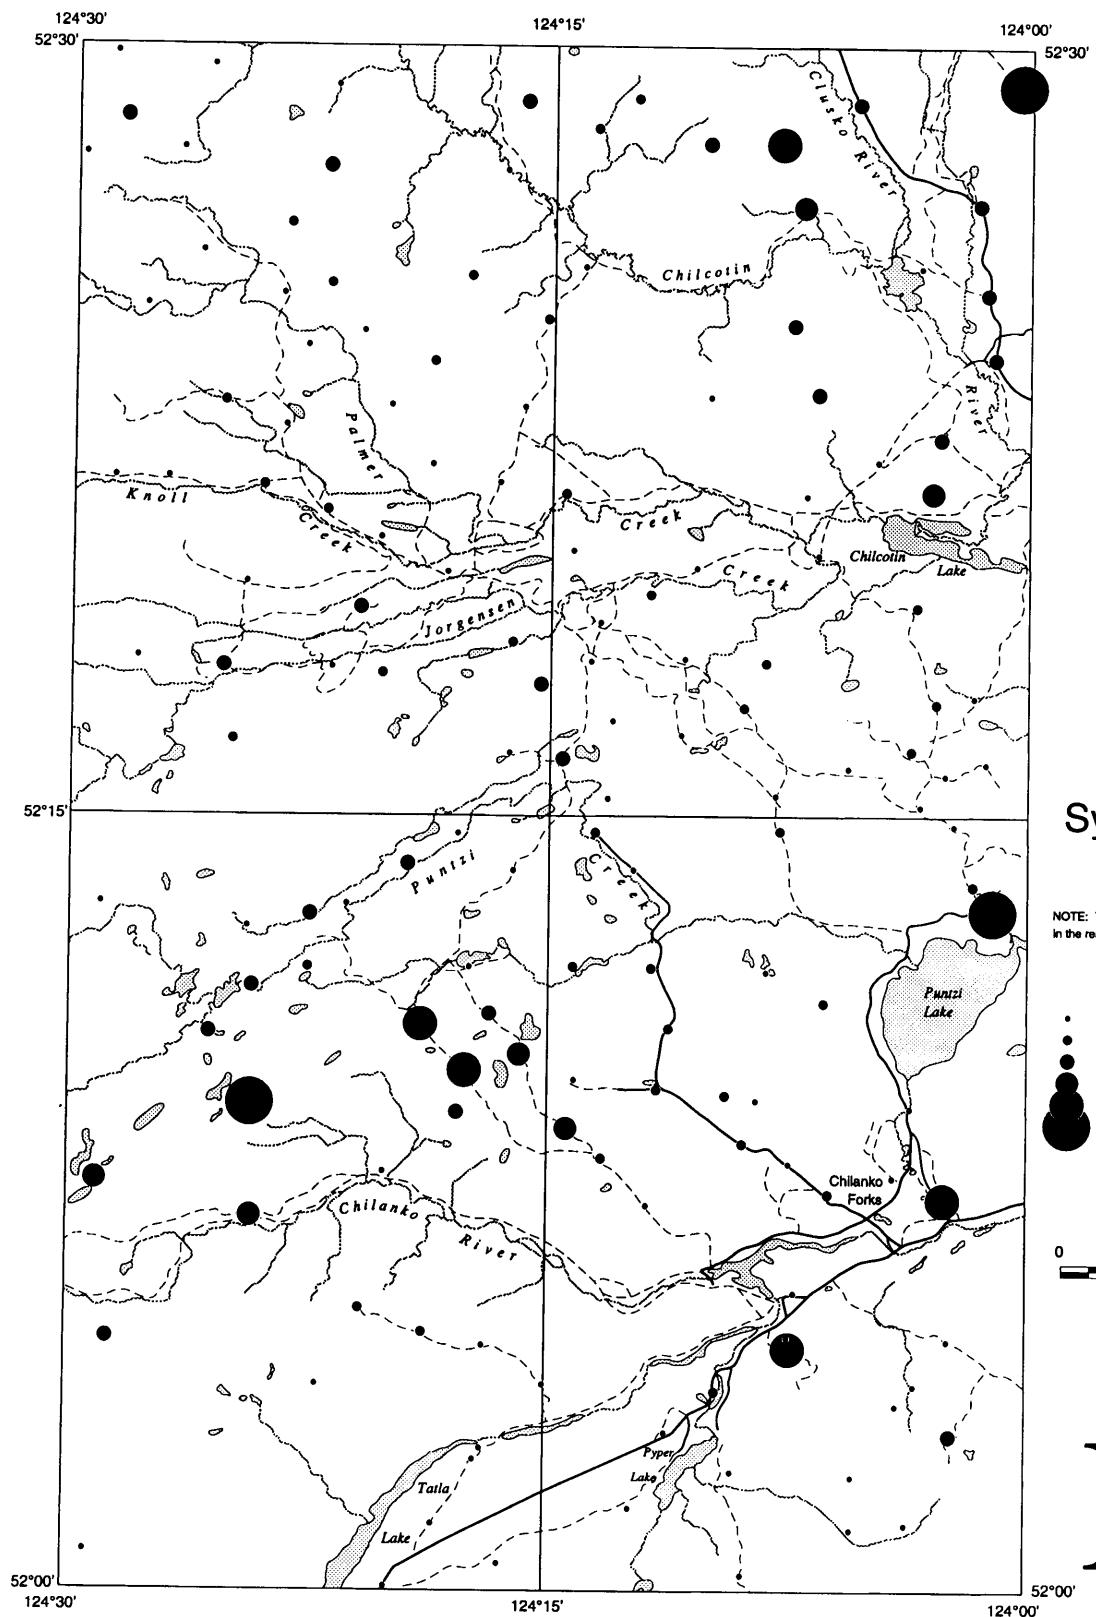

Normal Probability Curve

Summary Statistics

Number of samples: 154
Minimum: <15
Maximum: 72
Mean: 30.0
Mode: 10
Median: 31
Lower quartile: <15
Upper quartile: 40
Standard deviation: 16.6
Coefficient of variation: 1.8

Till Geochemistry of the Chilanko Forks - Chezacut Map Areas, B.C.
 NTS 93C/01 and 93C/08

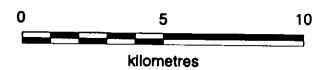

Symbol Legend

Rubidium (ppm)

NOTE: The higher value in each symbol class is included in the respective interval, while the lower value is ignored.
