ABSTRACT

Open File 2001-07 describes the detailed surveys carried out by the British Columbia Geological Survey Branch in the Gataga District of north eastern B.C. to improve geochemical exploration techniques for sedex type Pb-Zn-Ag sulphide deposits and develop geochemical exploration models. Over 300 soil, rock, stream sediment, moss mat sediment, stream water and spring water samples were collected from five areas around Driftpile Creek including the Driftpile Creek Pb-Zn-Ag deposit (MINFILE 94K066), the Bear sulphide occurrence (MINFILE 94F024) and at the Spa Occurrence (MINFILE 94F003), a large, metal-rich surface ferricrete deposit. Rock, soil and sediment samples were analysed for more than 60 elements by methods that included instrumental neutron activation (INAA), aqua regia-inductively coupled plasma emission spectroscopy (ICPES) and sequential extraction analysis with hydroxylamine hydrochloride and hydrofluoric acid. Filtered, acidified water samples were analysed by inductively coupled plasma mass spectroscopy (ICPMS).

Iron-oxide spring deposits and soil close to the sedex mineralization at Driftpile Creek and the Bear occurrence have high Pb, Ag, Ba, Hg and Tl content. The spring water is acid and has elevated Ba, Al, Pb, and Tl. Other iron-oxide spring deposits such as the Spa have very high As, Cd, Co, Ni, Mo, U and V. Spring waters are alkaline and have high Ca, As, Cd, Co, Ni, Mo, U and V. Both acid and alkaline spring water samples have high Zn and SO₄. Sequential extraction analysis reveals that Co is associated with Mn-oxides in spring deposits whereas Mo, Ni and Zn are bound to Fe oxides. The partitioning of Pb into the different Fe-oxide phases changes as the maturity of spring deposits increases. Moss mat sediment generally has higher Pb and Ba than stream sediment. The multi-media geochemistry suggests that there may be additional sedex Pb-Zn mineralization near Saint Creek, north of Driftpile Creek and in an area north of the Bear occurrence where there is also evidence of Au mineralization. A geochemical exploration model (GEM) developed from survey results more clearly identifies the different sources for the metal and the barriers that give rise to geochemical anomalies.

INTRODUCTION

This Open File describes the results of detailed studies carried out by the British Columbia Geological Survey Branch in the Gataga District of north eastern BC (Figure 1) to study the geochemical response of massive sulphide mineralization in stream sediment, moss mat sediment, spring sediment, spring water, soil and till. These studies were carried out in conjunction with geological mapping and mineral deposit studies (Ferri *et al.* 1995). Lett and Jackaman, 1995, reported the results of geochemical orientation studies around Driftpile Creek. The detailed geochemical studies reported in this Open File were carried out to improve geochemical exploration techniques for shale-hosted sedex Pb-Zn-Ag deposits and to develop geochemical models for simplifying data interpretation.

The Open File is published in two Parts. Part 1 describes a geochemical exploration model (GEM) for sedex Pb-Zn-Ag sulphide deposits in the Gataga District developed from detailed survey data for five areas north and south of the Driftpile Creek deposit. The geology, topography, soils and survey results for the areas are summarized in Part 1. Survey results are augmented by assessment report data. Part 2 describes the results of the geochemical surveys in more detail with all of the supporting field and analytical data. Essentially, Part 1 provides a "Readers Digest" of the information compiled in Part 2.

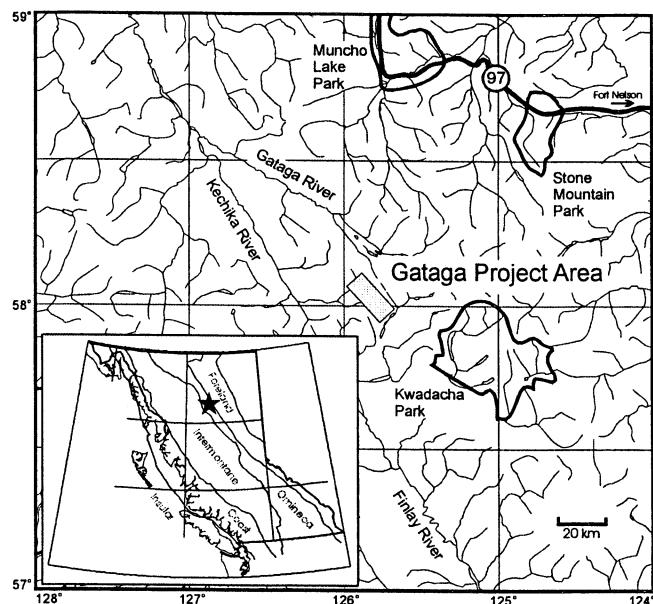

Figure 1. Location of the project area

PART 1

BACKGROUND

A problem commonly encountered in geochemical exploration for shale-hosted Pb-Ag-Zn deposits is that very high Zn and Ag background levels mask the surface expression of the sulphide mineralization. The high Zn-Ag backgrounds reflect subsurface weathering and oxidation of metal-rich, carbonaceous and pyritic shale that releases metals (e.g. Fe, Zn, Co, Ni, U, V) into ground water. Metals accumulate in soil and sediment by clastic dispersion of weathered shale fragments, by adsorption from ground water solutions to clay and secondary Fe-Mn minerals and by precipitation. Surface discharge of acid ground water, produced by oxidation of the pyritic shale can give rise to secondary Fe oxide spring precipitates and ferricrete deposits. Depending on the pH and Eh of the near-surface environment, the secondary iron oxide minerals can accumulate up to several thousand ppm of As, Ba, Cu, Pb and Zn (Hassen and Boure zug, 1990).

The very colourful surface Fe-oxide deposits in shale basins can give a misleading impression of the actual base metal sulphide mineral potential of an area. In the Gataga District the numerous Fe-oxide spring deposits are associated with ground water draining Palaeozoic basinal-facies clastic rocks that host the Stronsay (Cirque), Bear and Drift pile Creek Pb-Zn-Ag-Ba sedex deposits (MacIntyre, 1992). Soils and stream sediments can contain several thousand ppm of Zn with significant amounts of Ag, Mo and other metals.

Previous studies in northern BC, the Yukon Territory and Alaska have recognized the problems of geochemical exploration for shale-hosted sulphide deposits. Carne (1983) established thresholds of 175 ppm Pb, 700 ppm Zn and 0.6 ppm Ag in soil around the Drift pile Creek deposit. Iron-oxide spring deposits in the area were found to have one percent Zn, and 400 ppm Pb with elevated As and Mo. The highest concentrations in iron oxide spring deposits occur where the deposit has formed from neutral to alkaline ground water. Where ground water is acid Fe-oxide spring deposits are smaller and do not accumulate Co, Cu, Ni or Zn to high concentrations (Fletcher and Doyle, 1974). Other surface water pH related changes in shale basins include the formation of a white coloured precipitate (aluminium hydroxide) coating stream sediment (Earle, 1976).

A variety of spring deposits occur in the Gataga District. The most common are:

- Small (10-20 cm high) mounds surrounding the actual spring discharge. The 'cold-spring' mounds consist of laminated red to dark brown Fe-oxide terracettes (Plate 1).
- Surface crusts of laminated Fe-oxide that are probably derived from the physical erosion of the cold spring deposits. The surface crusts also consist of variegated, friable Fe-oxide sinter that can form slabs scattered over the surface of vegetation kill zones (Plate 2).
- Ferricrete deposits consisting of rounded Paleozoic pebbles and cobbles cemented with sandy

textured ferruginous material. These deposits may be several metres thick and can extend for several hundred metres along the side of creeks.

Typically, no active springs are associated with the ferricrete deposits.

- White-coloured, laminated precipitate coating clastic sediment and vegetation debris in stream channels. This type of precipitate is less common than the ferruginous deposits and is most likely to consist of aluminium hydroxide or secondary barite. The precipitate is not generally found in surrounding springs, but is most visible in the channel several metres downstream from the spring (Plate 3).
- White-coloured, laminated travertine and calcrete

Analysis of different grain and density fractions from stream sediment samples previously collected in the Driftpile Creek area indicate that pH changes in the stream water result in separation of Pb from Zn sediment anomalies. This partitioning is due to the different geochemical mobility of two of the metals. Lead and Ba shales in heavy mineral fractions of stream sediments can help avoid high background effects with support from geochemical pathfinders such as Cd and Hg (Ballantyne, 1992).

Weathering of metal-enriched, fine clastic sedimentary rocks, erosion of surficial deposits and oxidation-solution of mineral sulphides are the principal processes by which metals are released into the near-surface environment.

Elements concentrate in streams as detrital minerals, by absorption to

secondary Fe or Mn oxides or by precipitation in response to changing stream water pH. Multi-media studies are designed to identify the metal sources and the processes leading to geochemical anomaly formation. The results of multi-media studies can be more easily explained and interpreted using a geochemical exploration model.

SEDEX DEPOSIT GEM

The geochemical exploration model (GEM) described in this Open File is based on a series of conceptual, three dimensional models first proposed by Bradshaw, 1974, for the Canadian Cordillera and later modified by Kauranne, 1976, Lovering and McCarthy, 1978 and Butt and Smith, 1980. Lett and Jackaman, 2000 and Lett, 2002 have used similar models to interpret geochemical data for volcanogenic massive sulphide (VMS) and platinum-rich sulphide deposits in southern B.C. A model summarizing the geochemical behaviour of elements in bedrock and the surface environment for sedimentary exhalative (sedex) Pb-Zn-Ag-Ba mineralization is shown in Figure 2. In Figure 2, the relationship between bedrock geology, sedex mineralization, surficial deposits (soil, till, etc.) and surface drainage is displayed three-dimensionally by a series of stacked, block diagrams. These diagrams are linked to a series of geochemical landscape layers showing the geochemical expression of mineralization traced from the bedrock interface into the surficial deposits, soil, stream sediment and water. The ice-flow direction and the projected expression of mineralization from the bedrock onto the layers are also shown on the diagrams.

Ideally, a mineral deposit primary trace element signature will be reflected in till, soil, vegetation, stream water and stream sediment geochemistry. Metals typically enriched in sedex sulphides (e.g. Hg, Cd, Pb, Se, Ag, Tl, Zn), in the sulphide host-rocks (e.g. Ba, Mn) and in carbonaceous shales (e.g. As, Co, Ni, Cu, Mo, V, U, Zn) are identified on the bedrock geochemistry layer. The element association shown in Figure 2 is partly based on the sedex deposit profile E 14 (Lefebvre and Ray, 1995) that is typical of base-metal deposits in the Gataga District (e.g. Driftpile Creek). Primary geochemical haloes shown on the bedrock layer have no scale because the actual lithogeochemical anomaly size varies from deposit to deposit.

Till and colluvial dispersal trains from sedex mineralization and metal-rich shale are displayed on the surficial geochemistry layer in Figure 2. An indication for the size and contrast of the till and colluvial anomalies is shown by shaded horizontal and vertical patterns. Element associations identified on the plumes are intended to distinguish between the different bedrock sources for the surficial anomalies such as Ag-Ba-Cd-Mn-Pb-Tl-Zn from sedex sulphide-barite deposits and As-Co-Ni-Mo-V-U-Zn from shale host rocks.

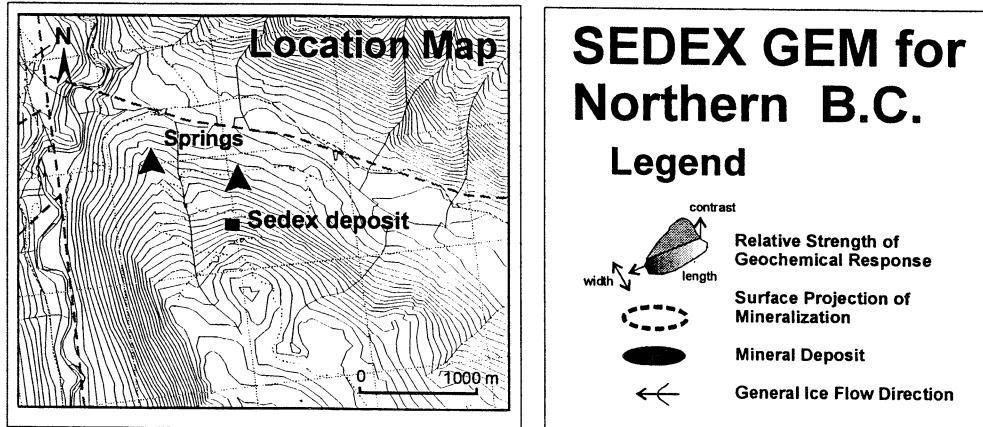

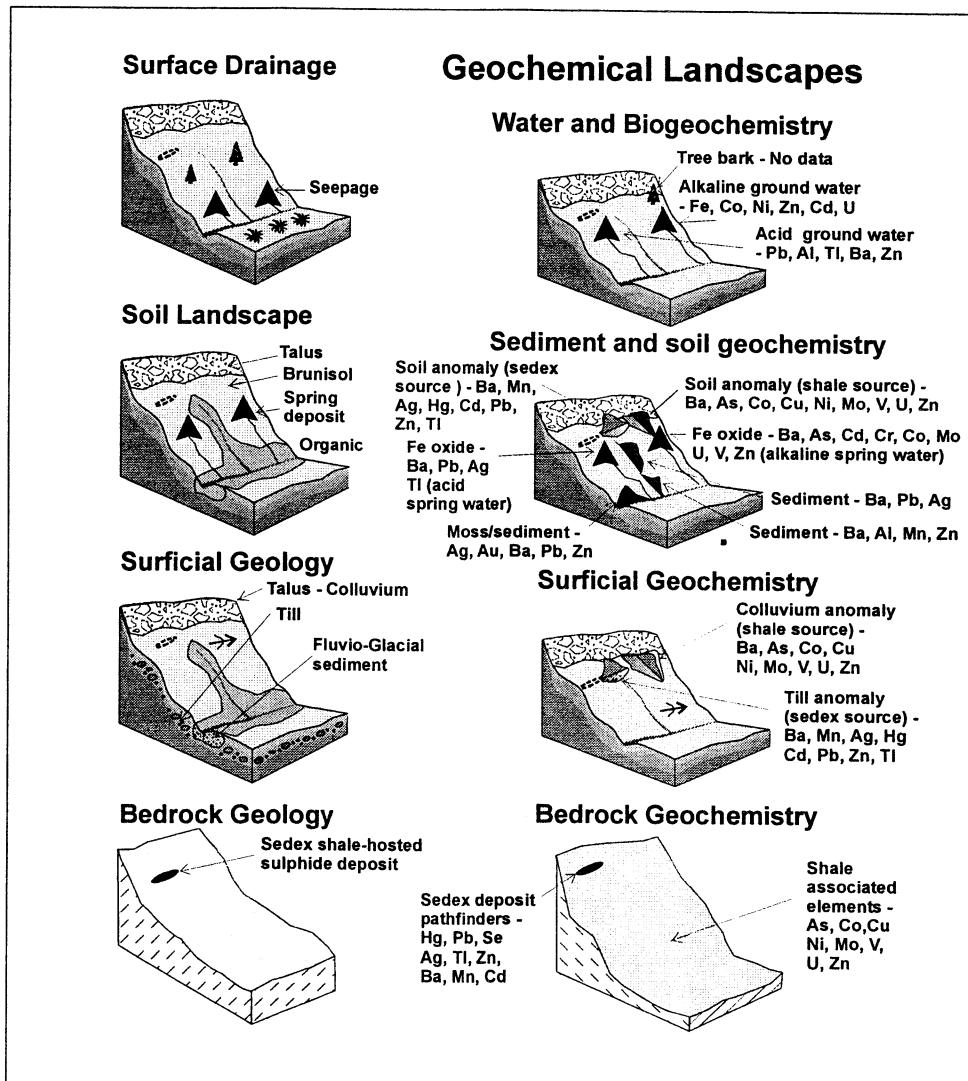

Figure 2. GEM for sedex Pb-Zn-Ag sulphide deposits

The soil landscape layer combines the topography, drainage and predominant soil types typical of the bioclimate zones and landscapes found in the Gataga District. The patterns on the soil-sediment geochemistry layer are intended to indicate the relative strength of geochemical response in B-horizon soil, stream sediment, spring deposits and spring water. In the B-horizon elements characteristic of sedex mineralization and shale bedrock are shown. Elements elevated in deposits associated with alkaline and acid spring water are distinguished on the soil geochemistry layer and water layer.

The geochemical exploration models described in this Open File are classified according to a hierarchical scheme similar to that proposed by Butt and Smith, 1979, and modified to be more applicable to British Columbia climatic zones, landscapes and surficial geology. Ideally, a GEM can represent data collected in mountainous, alpine areas (Topography Class A), more moderate relief (Topography Class B) and almost flat terrain (Topography Class C). Within each topographic class the different surficial sediments (e.g. basal till, colluvium) are assigned a number code. Table 1 shows the sediments in topography class C and the corresponding code for each type. The same sediment code is used in topography classes A and C, although some sediment types may not be represented. As an example, the GEM class C3 (high relief, colluviated till) shown in Figure 1 commonly represents the relief and surficial geology of the Gataga District.

Table 1. GEM classification for a high relief area

Code	Surficial Deposit

C11	Organic deposit (wetland, bog, fen)
C12	Glacio-marine sediment
C13	Residual sediment

SUMMARY OF DETAILED SURVEY RESULTS

The GEM presented in this Open File has been developed from geochemical surveys over six areas (Figure 3) in the Gataga District. These are described in detail in Part 2. In this section of Part 1 the information for each area, the survey results, relevant assessment report and other published data have been compiled in a standard format as follows:

- 1) Name and location (NTS Sheet, Lat, Long).
- 2) Geology
- 3) Mineralization
- 4) Topography, glacial deposits, soil types, vegetation
- 5) Soil geochemistry
- 6) Stream sediment and stream water geochemistry
- 7) Rock and other data

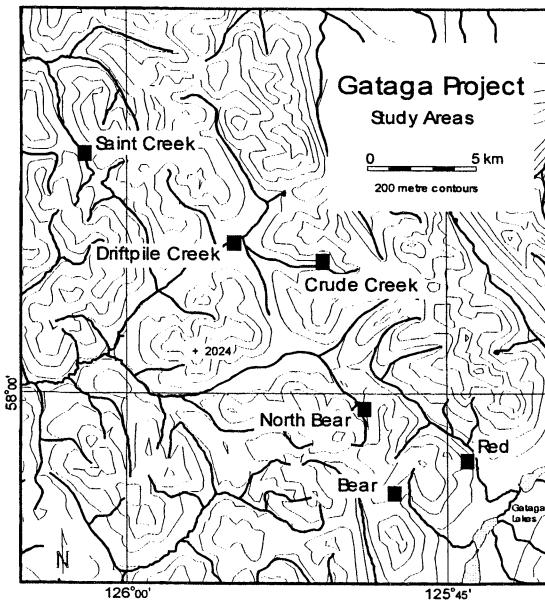

Figure 3. Location of detailed surveys

The soil landscape layer combines the topography, drainage and predominant soil types typical of the bioclimate zones and landscapes found in the Gataga District. The patterns on the soil-sediment geochemistry layer are intended to indicate the relative strength of geochemical response in B-horizon soil, stream sediment, spring deposits and spring water. In the B-horizon elements characteristic of sedex mineralization and shale bedrock are shown. Elements elevated in deposits associated with alkaline and acid spring water are distinguished on the soil geochemistry layer and water layer.

The geochemical exploration models described in this Open File are classified according to a hierarchical scheme similar to that proposed by Butt and Smith, 1979, and modified to be more applicable to British Columbia climatic zones, landscapes and surficial geology. Ideally, a GEM can represent data collected in mountainous, alpine areas (Topography Class A), more moderate relief (Topography Class B) and almost flat terrain (Topography Class C). Within each topographic class the different surficial sediments (e.g. basal till, colluvium) are assigned a number code. Table 1 shows the sediments in topography class C and the corresponding code for each type. The same sediment code is used in topography classes A and C, although some sediment types may not be represented. As an example, the GEM class C3 (high relief, colluviated till) shown in Figure 1 commonly represents the relief and surficial geology of the Gataga District.

Table 1. GEM classification for a high relief area

Code	Surficial Deposit

C3	Colluviated till
C4	Basal till - single ice advance
C5	Basal till - multiple ice advance
C6	Melt-out (ablation till)
C7	Glacio-fluvial sediment
C8	Glacio-lacustrine sediment
C9	Fluvial sediment
C10	Lacustrine sediment
C11	Organic deposit (wetland, bog, fen)
C12	Glacio-marine sediment
C13	Residual sediment

MAIN BEAR AREA

1. Location

NTS 94F/13E; 57° 57' 46" N 125° 47' 08" W. Soil, rock and spring water samples collected from the Bear occurrence (MINFILE 94F024) and along tributaries of Bear Creek (local names).

2. Geology

A thick sequence of unmetamorphosed upper Devonian Gunsteel Formation (Earn Group) black shales, siltstones, mudstones and turbidites strike northwest and, structurally, have been influenced by northeast directed folding and thrusting. The Gunsteel Formation is bounded to the west by the Waldemar thrust, which juxtaposes lower Devonian age chert-pebble conglomerate of the Besa River Formation with the Gunsteel Formation. The sulphide-barite mineralization occurs towards the base of the Gunsteel Formation (Evans, 1995).

3. Mineralization

Sulphide mineralization has been traced by diamond drilling for more than 600 metres along strike and has been intersected over 200 metres below the surface. The mineralized zone in the Gunsteel Formation consists of basal cherts and graphitic shales containing pyrite laminations with disseminated galena and sphalerite. Above these rocks are massive barite, Ag-Pb-Zn-sulphides and pyrite. The massive sulphides are overlain by graphitic and siliceous shale containing laminated pyrite, carbonate and barite. At the top of the sequence is black shale containing carbonate, barite and pyrite nodules that grade into well-laminated turbidites. Grades of 1.6 gram/tonne Ag, 5.28 per cent Zn and

0.11 per cent Pb, over 6.0 metres have been reported by Evans, 1995, in the massive sulphides.

4. Topography, glacial deposits, soil types, vegetation

The Bear occurrence is in an area of high relief on a southeast facing hill slope at an elevation of 1600 metres. A barite covered "kill-zone" represents surface expression of the sulphide mineralization. There are also scattered, weathered sulphide showings and numerous Fe oxide spring and ferricrete deposits along creeks draining the occurrence. Above tree-line (1500 metres) outcrop is almost continuous or covered by felsenmeer and talus fans. At lower elevations colluvium and/or glacial sediments cover bedrock.

5. Soil geochemistry

An assessment reported soil survey (Carne, 1983) over the area underlain by the sulphide mineralization outlined a northwest trending Pb anomaly (>175 ppm) up to 500 metres long and 100 metres wide. The highest Pb concentration reported in the soil was 4000 ppm and the anomaly peak was only metres from the surface projection of the sulphide mineralization. Zinc soil anomalies (>700 ppm), however, were several hundred metres down slope from the mineralization. Silver anomalies (>0.6 ppm) showed a similar pattern to Pb. New geochemical data indicates that high Ba (27,000 ppm), Pb (13,466 ppm), and Ag (30.2 ppm) levels are present in the B and C soil horizons. These levels persist for 300 metres across the projected surface extension of the massive sulphide body. The soil also has up to 9050 ppb Hg, 13 ppm Se, 14 ppm Sb, but less than 1000 ppm Zn. Barium

values determined by aqua regia-ICP in soil over the mineralization are below 100 ppm compared to levels up to 28,000 ppm Ba by INAA. This difference reflects the high contact of acid resistant barite in the soil.

6. Stream sediment and water geochemistry

An assessment reported stream sediment survey (one sample/100 metres) showed that Pb decreased from one percent near the sulphide mineralization to 300 ppm at a point 800 metres downstream. Zinc values exceeded 1000 ppm for 2.3 kilometres and the stream sediment Zn threshold was estimated to be 500 ppm (Carne, 1983). New geochemical data show that stream sediment close to the Bear Creek source contains 15,000 ppm Ba, 4949 ppm Pb and 73 ppm Ag. The Ba values fall to 13,000 ppm below the confluence of the two branches of Bear Creek. Barium, Pb and Ag are higher in moss mat sediment samples compared to stream sediment. Lead values are over 200 ppm along a 3 kilometre reach of Bear Creek and zinc values increase erratically downstream from mineralization. Spring water draining into the upper part of the Bear creek is acid (< pH 5) and has up to 392 ppb Pb, 2.73 ppb Tl and 119 ppm SO₄. Acid water (pH 3.85) from another spring contains 1398 ppb Al and has a thick, white precipitate coating the sediment.

7. Rock geochemistry

Fe-rich spring sediment, ferricrete and soil samples have high As, Sb, Ba, Co, Cr, Mo, Ni, Pb, V and Zn. The matrix of ferricrete close to the Bear occurrence has up to 37,000 ppm Ba, 1256 ppm Pb, 2500 ppb Hg, 3 ppm Ag, but less than

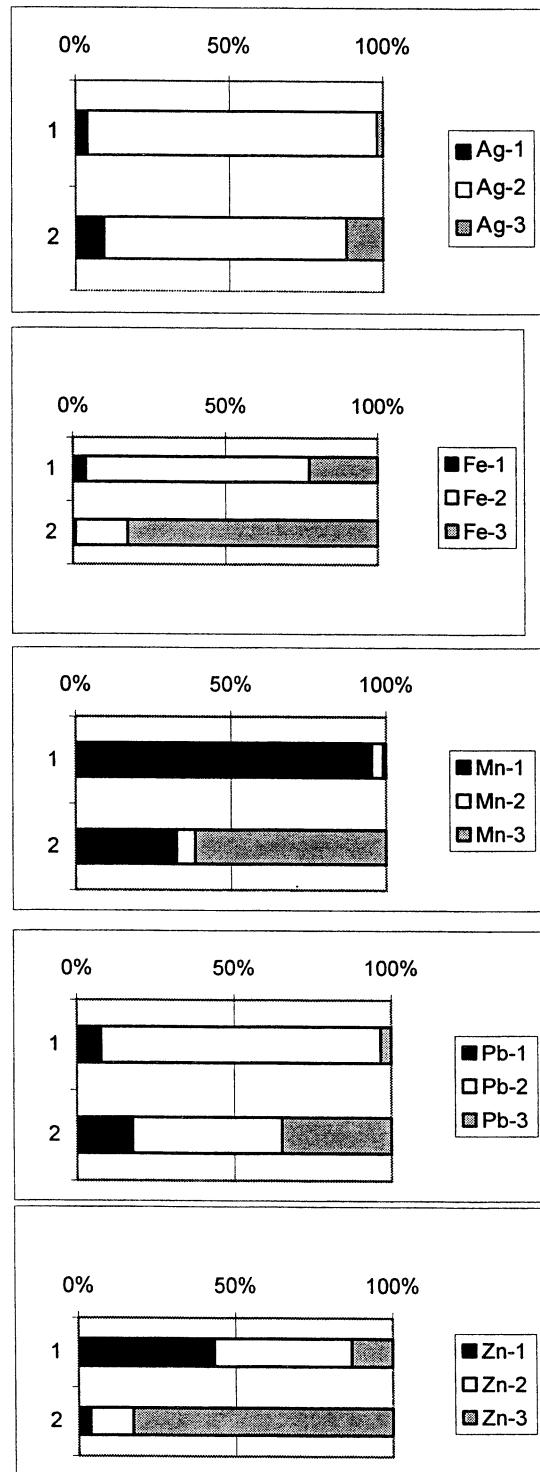

Figure 4. Percent metal extracted by 0.25M NH₂OH HCl (1) 1M NH₂OH HCl (2) and HF-HCl-HNO₃ (3) from fresh Fe oxide precipitate (1) and mature ferricrete (2) from the Bear area.

300 ppm Zn. Recently formed, laminated Fe-oxide by a spring on the east branch of the creek has less than 3000 ppm Ba, but more than 10,000 ppm Pb and 32 ppm Ag.

More of the total Fe, Zn and Co is dissolved by 1M NH₂OH HCl from recent Fe-oxide spring deposit (sample 945017) than from a mature ferricrete deposit (sample 945024). However, more Fe is extracted from ferricrete by HF-HClO₄-HNO₃-HCl acids compared to 1M NH₂OH HCl. (Figure 4). More Zn Co and Mn are also released by the 0.25M and 1M NH₂OH HCl from the Fe-oxide spring deposit compared to the ferricrete suggesting that, as the deposit matures, metals become associated with the most resistant minerals. A higher proportion of Pb and Ag are extracted by 1 M NH₂OH HCl from the recently formed Fe-oxide spring deposit compared to amounts dissolved from ferricrete. This suggests that Pb is more mobile in the early stages of deposit formation and may be relatively weakly bound to the oxide surface or precipitated as Pb sulphate.

NORTH BEAR AREA

1. Location

NTS 094K/4 and 094K/13. 58° 00' 00" N 125° 49' 00" W. Soil, rock, spring water, stream water, stream sediment and moss mat samples were collected along a valley north of the Bear occurrence.

2. Geology

The Gunsteel and Besa River Formations underlying the valley consist of non-siliceous, thick-bedded gritty black shale, a medium to thick bedded,

siliceous and non-siliceous shale and a cherty black argillite containing barite, traces of pyrite, galena and sphalerite. The Gunsteel Formation is in thrust contact with silty black shale and conglomerate of the Besa River Formation to the west. The valley forms the axis of an overturned syncline and the contact between the Gunsteel and Besa River Formation is commonly a low-angled, west-dipping thrust fault. Ferricrete deposits are common along both sides of the valley around springs discharging along faults.

3. Mineralization

The only reported sulphide mineralization is the Bob occurrence (MINFILE # 094K085) where barite-Pb-Zn-rich massive pyrite occurs in tightly folded, thinly bedded black shale, cherty argillite, and baritic-pyritic mudstone. The BOB occurrence is north of the area covered by the detailed sampling.

4. Topography, glacial deposits, soil types, vegetation

Numerous Fe oxide spring and ferricrete deposits are scattered along both sides of a U shaped valley. Above tree-line (1500 metres) outcrop is almost continuous or covered by felsenmeer and talus fans. At lower elevations bedrock is covered with colluvium or till that was most likely deposited by ice advancing parallel to the valley axis. Alluvium and glacio-fluvial deposits are also present on the valley floor. Several of the first-order streams draining into the main creek have a thick, white precipitate coating boulders and bottom sediments.

5. Soil geochemistry

Iron-rich spring deposit and ferricrete samples are typically enriched in As, Sb,

Ba, Co, Cr, Mo, Ni, Pb, V and Zn. One Fe-rich soil sample close on the east site of the valley has elevated Au - 63 ppb and Pb - 2708 ppm. Weakly acid spring water near the Au-rich soil, has elevated Fe, Sb and As and graphitic shales have up to 157 ppb Au, 233 ppm Pb, 0.7 ppm Ag and 45 ppm Sb.

6. Stream sediment and water geochemistry

Anomalous Au, As, Sb, Pb, Zn and Hg occur in moss mat sediment for 2 kilometres along the stream. Spring waters are acid (pH 4.44), oxygenated (DO 8.3 ppm) with high Pb, Tl, Al, Co, Ni, Cd, Zn, and rare earth element contents or are weakly alkaline (pH 7.2), oxygen depleted (DO 0.2 ppm) and have a high Fe content. A thick Fe-oxide precipitate surrounds alkaline springs whereas acid springs have thick, white precipitate coating sediment.

7. Rock geochemistry

Rocks have Ba (INAA) levels above 2.1 percent and up to 3.8 percent. Highest concentrations are from the east side of the valley. However, the Ba-rich rock only has weakly anomalous (< 90 percentile) Pb, Zn and Ag levels.

RED GOSSAN (SPA SHOWING) AREA

1. Location

NTS 94K/13E. 57° 57' 45" N 125° 44' 00" W. MINFILE 94F 003. Samples were collected in the valley of a south flowing creek. Sampling focused on several large iron spring deposits on the west side of the valley.

2. Geology

The most impressive surface feature of the Spa showing is a large area (350 by 100 metres) of dry Fe oxide sinter up

to 6 metres thick that most likely reflects a past episode of Fe precipitation from ground water flowing from a west dipping thrust fault. The sinter is underlain by gritty black shale and siltstone of the Besa River formation (the eastern equivalent of the Earn Group).

3. Mineralization

Sub-surface mineralization at the Spa showing consists of secondary zinc minerals (hydrozincite, melanterite) along fractures in the shale, barite beds, nodular barite and a thin (5 mm) barite-sphalerite-arkerite vein. Minor disseminated and laminated pyrite has also been reported (Somerville, 1980).

4. Topography, glacial deposits, soil types, vegetation

A large dry, surface Fe-oxide deposit (the Spa Mineral Showing) extends over several square kilometres at 1200 metres elevation on the west side of the valley. The creek in this valley flows south into Gataga lakes. There are a number of smaller Fe-oxide deposits associated with active springs roughly two kilometres to the north. Glacial sediments are most likely till deposited on the gently-sloping valley side surrounding the dry Fe oxide-deposit. Vegetation consists of alpine fir, black spruce and alder at lower elevations and scattered alpine fir and willow above 1500 metres.

5. Soil geochemistry

Soil sampling and diamond drilling carried out by Archer, Cathro and Associates in 1980 detected percent levels of zinc in soil samples from the Spa Showing (Somerville, 1980).

On the surface at the Spa showing deposits consist of loose, Fe-oxide cemented shale clasts. Beneath this Fe-oxide sinter is an Fe-stained blocky clay containing mixed with shale clasts. New geochemical data shows that Ag, Cd, Co, Fe, Hg, Mn, Ni, U and Zn are higher in the surface deposits sinter compared to underlying clay-rich sediment whereas As, Ba, Cr, Cu, Mo, Sb and V increase down the profile (Figure 5).

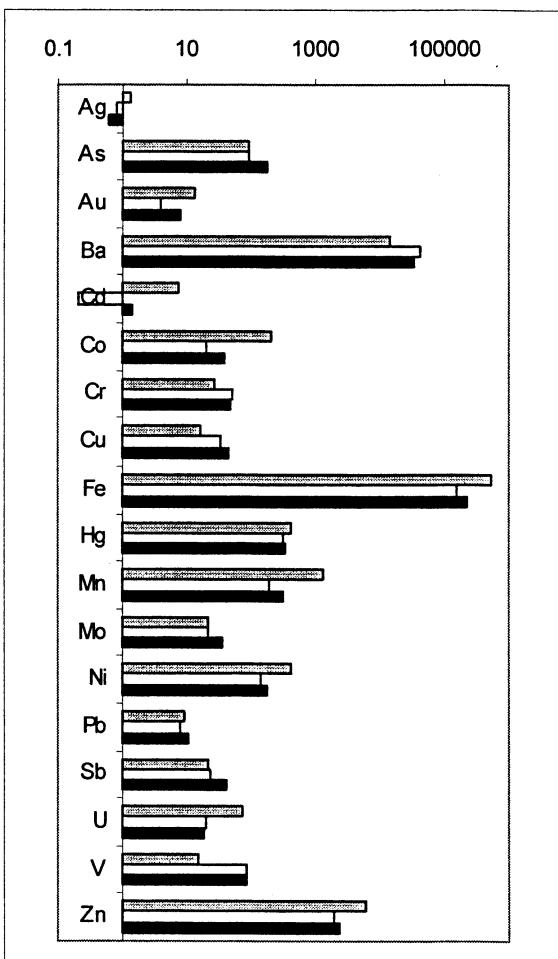

Figure 5. Distribution of elements at 0.3, 0.65 and 0.75 metres depth, Spa Showing. Au and Hg in ppb. Other elements in ppm.

The surface sinter contains up to 60 percent Fe up to 6.4 percent Ba with several 100 ppm As, Sb, Co, Cr, Ni, Mn, Hg, Mo, Ni, W, V and U. Iron oxides

deposited around active springs north of the Spa showing have similar metal concentrations. However, the highest Pb in the sinter and Fe spring deposits is only 23 ppm whereas Ag reaches 13 ppm.

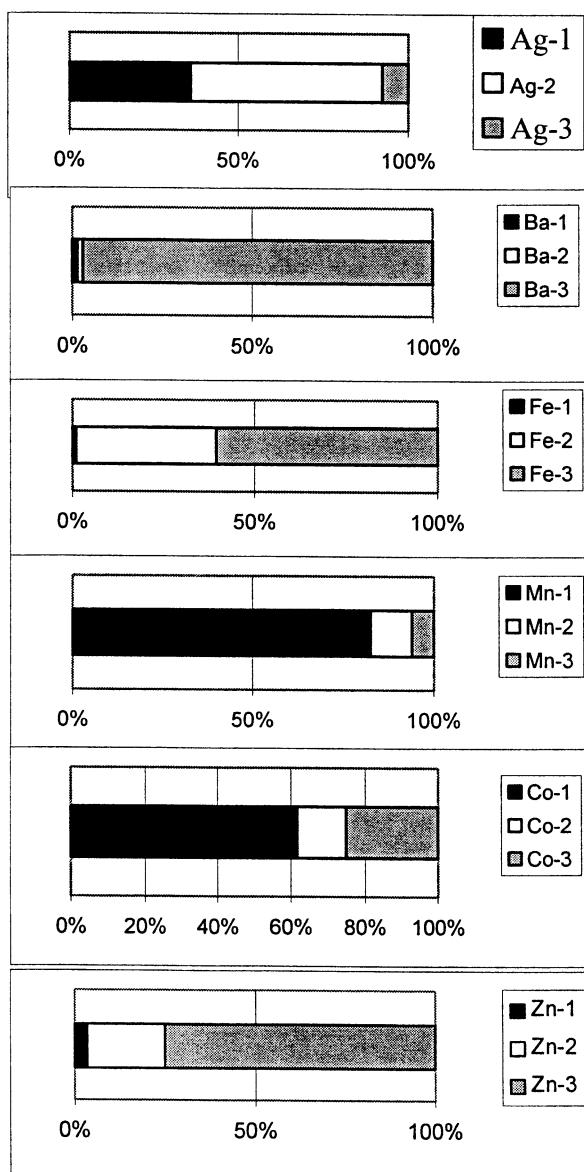

Figure 6. Percent metal extracted by 0.25M $\text{NH}_2\text{OH HCl}$ (1) 1M $\text{NH}_2\text{OH HCl}$ (2) and HF-HCl-HNO_3 (3) from Fe oxide surface sinter on the Spa showing.

Sequential extraction analysis shows that more than 90 per cent of As, Ba, Mo and V is bound in the most resistant fraction (HF-HClO₄-HCl-HNO₃ extractable) of the soil (Figure 6). However, more Zn, Ag, Co and Ni is extracted by NH₂OH HCl₂ suggesting that these metals were abundant in ground water flowing when the springs were active and were absorbed by Fe hydroxides during an early phase of sinter formation.

6. Stream sediment and water geochemistry

The active springs near the Spa prospect are along the west side of the valley two kilometres to the north where the spring water is typically neutral to weakly alkaline, high in Ca, Mg, Sr, Fe and SO₄ and has low dissolved O₂ levels. Concentrations to 466 ppb Ni, 21 ppb As, 4000 ppb Zn and 91 ppb Cd occur in the spring water, but Pb levels are below 0.2 ppb.

7. Rock Geochemistry

No Data.

DRIFTPILE DEPOSIT - CRUDE CREEK AREA

1. Location

NTS 92K/13. 58° 03' 59" N 125° 54' 35" W UTM: MINFILE 94K066

2. Geology

Nelson et al., 1995, have described the geology of the Driftpile deposit (MINFILE # 94K066). Massive sphalerite, galena and pyrite occur in blue-grey weathering, carbonaceous black shale and silty mudstone, cherty argillite and radiolarian chert of the Gunsteel Formation. The rocks are preserved in a broad, northwest-trending,

tightly folded synclinorium that has been disrupted by moderately dipping, northeast verging, thrust faults. Gunsteel Formation clastic sediments are interbedded with barite and/or pyrite-enriched siliceous shale or cherty argillite. The barite is nodular, disseminated, intercalated as thin laminae, or present as massive, centimetre-scale beds. Pyrite is generally laminated in mudstone, or associated with barite, or present as carbonate concretions. The Gunsteel Formation is in contact with the underlying Ordovician to lower Devonian Road River Group within the hanging-wall of the Mount Waldemar thrust fault to the south west of Driftpile Creek.

3. Mineralization

The Driftpile deposit (MINFILE 94K066) consists of at least two stratiform sulphide-carbonate and barite bodies. The lower or 'main' zone up to 70 metres thick is primarily a sulphide-carbonate facies interbedded by black graphitic shale or mudstone. Within the zone fine-grained, finely laminated or framboidal pyrite is associated with irregular bands and concretions of calcite. Sphalerite and galena can occur with the pyrite, but are most abundant as a layer of fine-grained massive sulphide near the base of the zone.

The 'upper' zone, 100 to 200 metres higher in the Gunsteel formation, consists of barite-sulphide mineralization, in siliceous or non-siliceous mudstone with pyritic laminations. Barite occurs in massive beds or laminations, or in nodules. Pyrite is subordinate to barite, but may form massive layers, locally accompanied by abundant sphalerite and galena.

Previous diamond drilling has established that sulphide mineralization typically grading 10 per cent Zn and 1 per cent Pb extends down dip for at least 100 metres, can be traced over a strike length up to 3 kilometres and has a surface width of 1.5 kilometres. The most recent reserve estimate (lower mineralized sub-unit of the 'main zone') is 2.44 million tonnes averaging 11.9 per cent Zn and 3.1 per cent Pb.

The DR barite occurrence (MINFILE # 94K077) is 2.5 kilometres southeast of the Driftpile deposit on Crude creek. Mineralization consists of nodules and thin lenses of massive barite in blue-grey weathering black shale and siliceous argillite of the Gunsteel Formation.

4. Topography, glacial deposits, soils and vegetation

The Driftpile Creek barite-Pb-Zn deposit is located near the headwaters of Driftpile Creek close to the western edge of the Muskwa Ranges. Driftpile Creek flows to the west through a winding U shaped valley into the Kechika River. Terraces and ridges at the 1350-metre elevation along both sides of the Driftpile Creek valley indicate proglacial lakeshore and fluvio-glacial sediments. The terraces mark a gradient change from steeper slopes close to the valley floor to a more subdued upland topography.

Sulphide mineralization is rarely visible at surface. However, there is one limonitic gossan capping an outcrop containing sulphides close to Driftpile Creek ("Discovery Zone"). This gossan has an associated barite "kill zone". In addition, several other "kill zones", iron-

spring and ferricrete deposits occur along the Driftpile creek valley and also close to the headwaters of Crude Creek, a tributary of Driftpile Creek.

5. Soil geochemistry

Soil and gossan material from two vertical profiles at the "Discovery Showing" kill zone have up to 7900 ppm Pb, 6400 ppm Zn, 34,000 ppm Ba

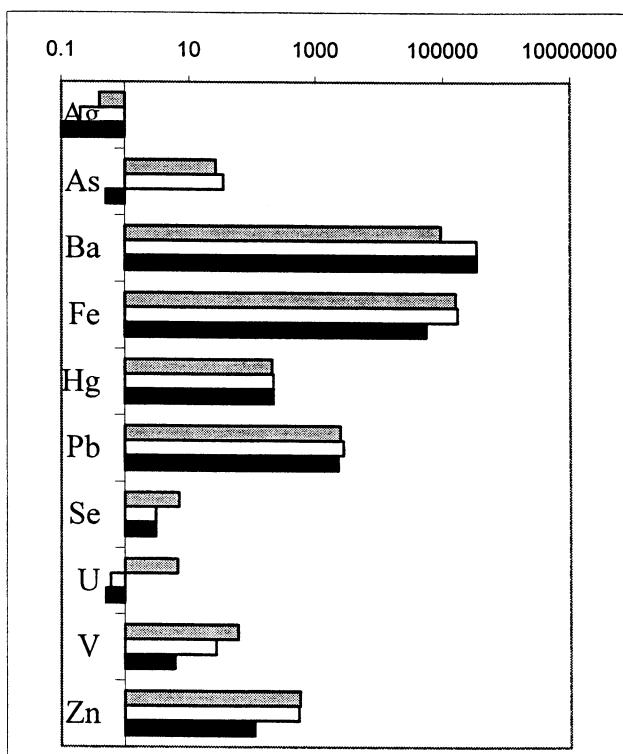

Figure 7. Distribution of elements at 5 cm, 15 cm and 25 cm depth, Driftpile "Discovery" zone. Hg is in ppb. Other elements are in ppm.

and 0.5 ppm Ag. A soil profile on the "Discovery Showing" (Figure 7) shows that Fe and Zn decrease sharply from elevated levels in the gossanous surface material to lower concentrations in the underlying mottled soil whereas Pb, Hg and Ba are almost constant down the soil profile. Results of the sequential extraction

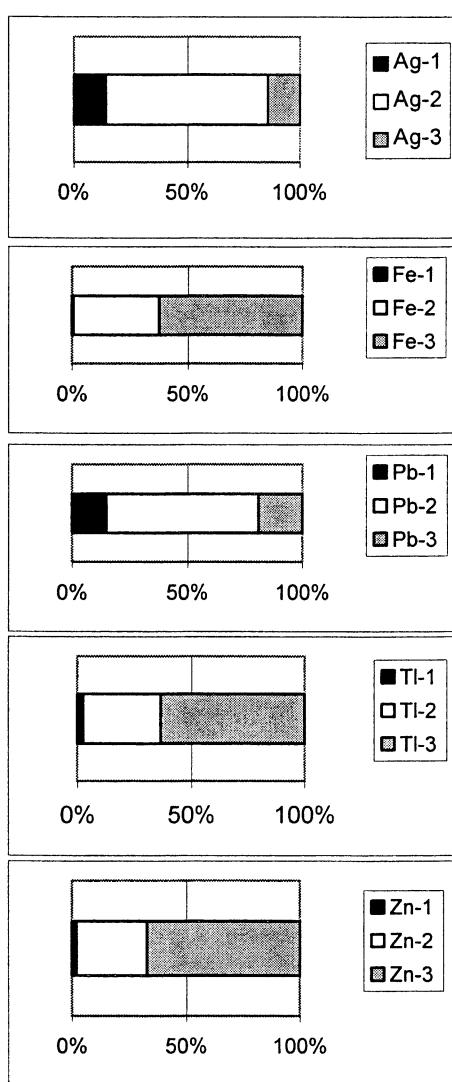

Figure 8. Percent metal extracted by 0.25M NH_2OH HCl (1) 1M NH_2OH HCl (2) and HF-HCl-HNO₃ (3) from soil sample at 5 cm depth surface on the Driftpile "Discovery" zone.

analysis (Figure 8) indicate that Pb and Ag are bound in the 0.25 M NH_2OH HCl fraction whereas Zn, Tl and Fe are dissolved by 1 M NH_2OH HCl and HF-HClO₄-HCl. The association of Zn, Tl and Fe as distinct from Pb and Ag in

the extracts suggests that the soil contains galena or Pb sulphate. Sphalerite has been largely oxidized to more soluble secondary Zn minerals that have been incorporated in Fe oxides.

6. Stream sediment and water geochemistry

The Driftpile deposit was discovered in 1973 following a 1970 regional stream sediment geochemical survey carried out by Geophoto Consultants (Wise, 1974). New data allows a comparison of stream sediment and moss mat sediment geochemistry for streams draining Pb-Zn sulphide mineralized (e.g. Driftpile deposit area) and non-mineralized areas (e.g. Crude Creek). Elements typically concentrated in heavy minerals (e.g. Ag, Au, W, Pb) are higher in moss mat sediment compared to the stream sediment. However, this trend is not always consistent. Other elements (e.g. As, Ni, Zn, Mn, Cd, Cu, Mo) are higher in the stream sediment compared to the moss mat sediment or show no obvious preference for sample media. Most moss and stream sediments have more than 1000 ppm Zn. However, only streams within 2 kilometres of the Driftpile creek deposit have more than 100 ppm Pb and 1 ppm Ag.

7. Rock Geochemistry

Ferricrete rubble covers the surface of a large "kill zone" roughly 150 metres by 30 metres in area located on the north side of the Driftpile Creek valley two kilometers east of the "Discovery" gossan. This "kill zone" is most likely underlain by rocks of the Upper Road River group. Results of sequential extraction analysis of samples from a

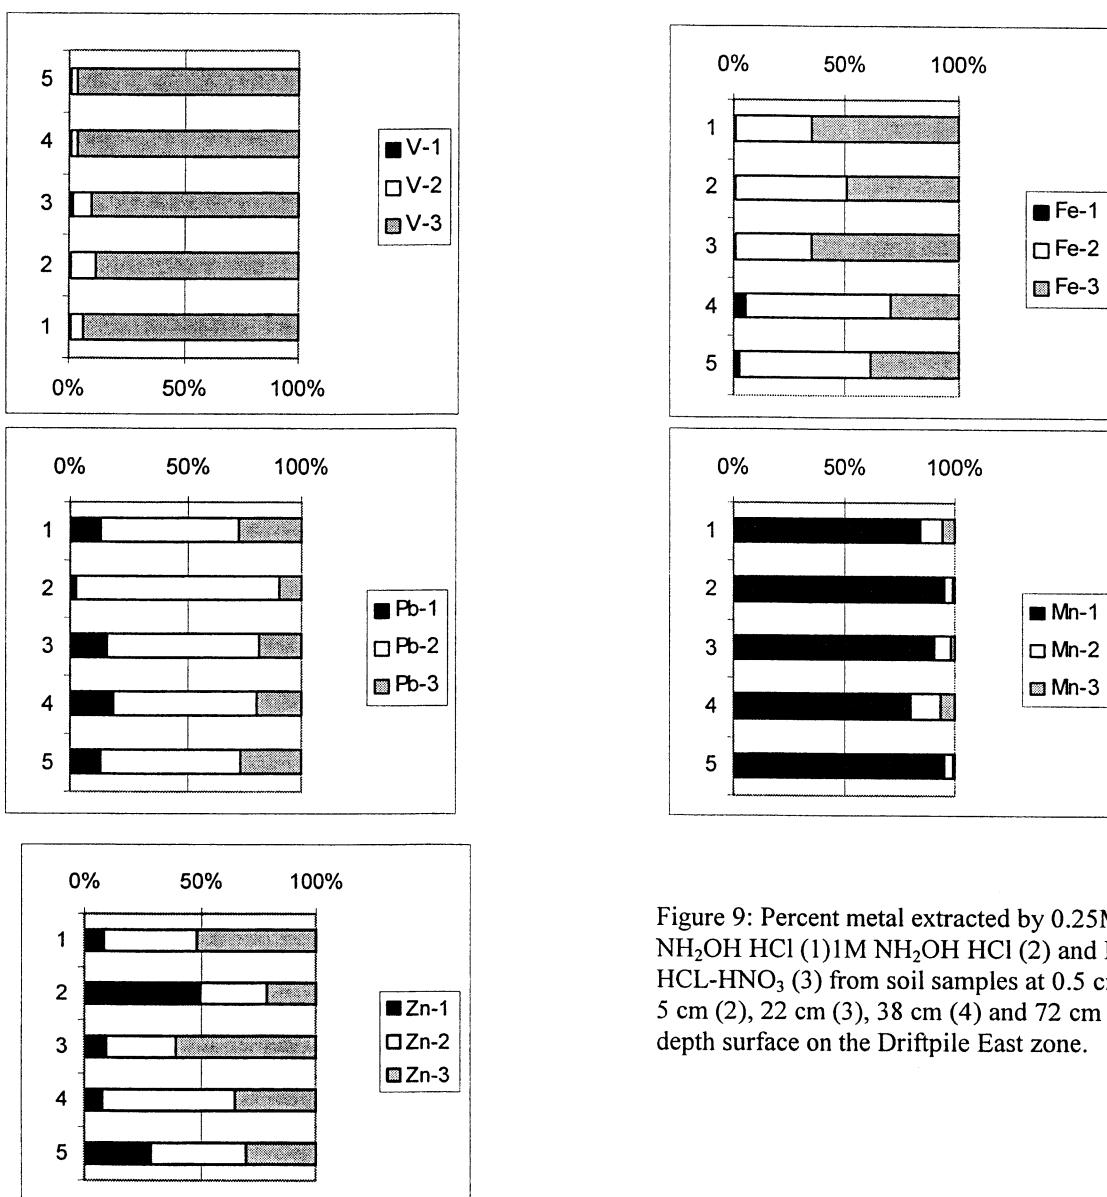

Figure 9: Percent metal extracted by 0.25M $\text{NH}_2\text{OH HCl}$ (1) 1M $\text{NH}_2\text{OH HCl}$ (2) and HF-HCL-HNO₃ (3) from soil samples at 0.5 cm (1), 5 cm (2), 22 cm (3), 38 cm (4) and 72 cm (5) depth surface on the Driftpile East zone.

SAINT CREEK AREA

1. Location

NTS 094K/4W. Latitude/Longitude: 58° 07' 26" N 125° 59' 07" W; UTM: zone 10 6446394 N 324188 E. Water, sediment and iron oxide spring deposit samples were collected along a valley west of Saint Creek (local name). The area was within the boundary of the Saint-Flaco mineral claims, a property staked by Archer and Cathro Associates in 1980.

2. Geology

Rocks of the Gunsteel Formation underlie the area north of the creek. Lithologies range from bluish-grey weathering carbonaceous cherty argillite, siliceous shale and bedded chert, with subordinate mudstone, to siltstone and coarser siliciclastics. Nodular, laminated or massive lenticular barite occurs at a number of horizons known to host Pb-Zn-Ag sedex mineralization at Driftpile Creek. The rocks are thrust faulted and tightly folded into a series of north easterly-overturned anticlines and synclines resulting in repetition of the baritic horizons on the surface. The Gunsteel rocks generally strike northwest and dip moderately to steeply southwest. In the southwest corner of the claims, a thrust juxtaposes dolomitic siltstones of the Ordovician-Devonian Road River Group onto the Gunsteel Formation. The iron-oxide spring deposits have up to one per cent Zn, but are not associated with the baritic horizons.

3. Mineralization

On the Saint-Flaco claims, barite-bearing strata have up to 5 per cent disseminated or laminated pyrite traces

of galena and sphalerite. (Carne, 1982; Insley and McClay, 1986).

4. Topography, glacial sediments, soils and vegetation

Iron-oxide spring deposits are located along the east side of a steep sided, narrow northwest-trending U shaped valley west of Saint Creek. The unnamed creek flows northwest through Braid Creek into the Kechika River. The valley sides are covered with talus and colluvium. Unsorted, coarse textured, glacial sediments fill the valley floor. The tree line reaches up to 1500 metres with mixed woodland and grassland in the valley bottom and alpine fir, black spruce and alder extending up the valley sides. Surface flora above 1500 metres consists of scattered alpine fir, willow and heather.

5. Soil geochemistry

Soil and Fe-oxide spring deposit geochemical surveys by Carne, 1983, over the Saint-Flaco claims outlined Pb and Zn soil anomalies. An area roughly 1200 metres by 400 metres on the west side of Saint creek is covered by soil that has above 175 ppm Pb. The Pb concentrations reach 6200 ppm and the anomaly trends northwest. Zinc levels above 1000 ppm and up to 10,000 ppm in soil occur in an area 1200 metres by 100 metres parallel to the creek. The peak of the Zn soil anomaly appears to be centred on the creek. Geochemical analysis of the Fe-oxide spring deposits was aimed at distinguishing between "exotic" anomalies caused by adsorption of metals from ground water and metals derived from sulphides in the underlying bedrock. The Fe-oxide spring deposits were found to have varying enrichment

in Pb, Zn, Mn, As, Mo, Co and Ni. Cobalt/Ni ratios in spring deposit samples were tested as a tool to distinguish between pyrite formed with VMS mineralization and diagenetic pyrite. The Co/Ni ratios for most samples were found to be less than 0.5. Higher ratios (> 0.5) were found in Fe-oxide spring deposits at the south end area close to the headwaters of the creek (Carne, 1983). A prominent source of metals in the Fe-oxide spring deposits was identified as ground water flowing from a thrust on the east side of the creek.

6. Stream sediment and water

Spring waters are mainly neutral to alkaline and have very high concentrations of Ca, Mg, Na, Fe, Co, Ni, Cd and Zn. The most acid spring water (pH 6.4) found is at the south end of the area and drains into the headwaters of the creek. This water also has the elevated Ba (83 ppb) and Al (361 ppm), but less than 0.1 ppb Pb.

Lead and Ba are higher in moss mat sediment compared to the stream sediment. However, this trend is not followed by other elements. For example, Cd and Hg are much higher in one sediment sample compared to the moss sediment from the same site. A low aqua regia-ICP extractable Zn value compared to 1720 ppm Zn by INAA accompanying the elevated Cd and Hg (1860 ppb) suggests the presence of sphalerite in the sediment. There are significantly elevated levels of Pb, Ba, Ag and Zn levels in stream sediment and moss mat sediment over 3 kilometre

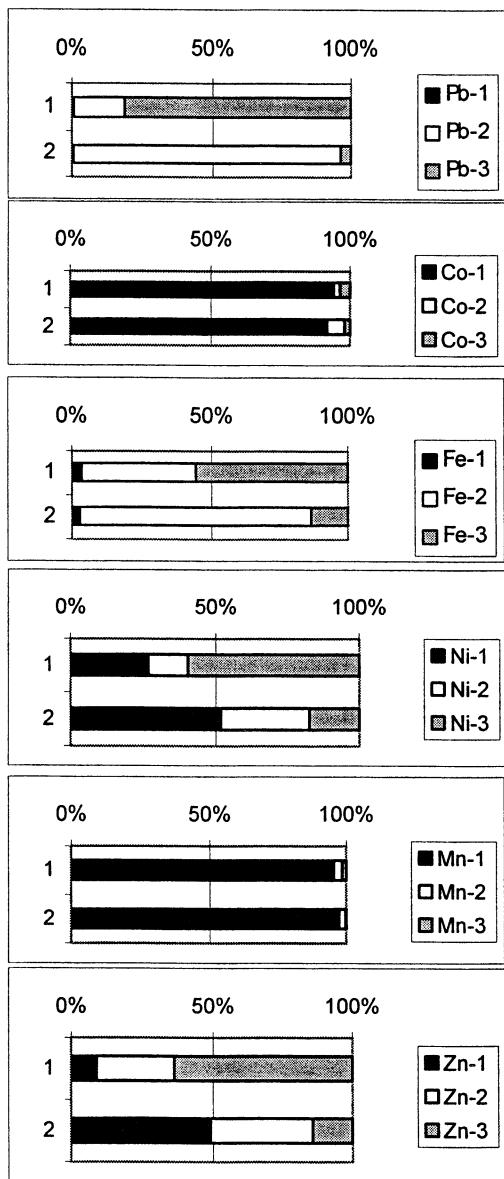

Figure 11. Percent metal extracted by 0.25M NH_2OH HCl (1) 1M NH_2OH HCl (2) and HF-HCL-HNO₃ (3) from a ferricrete sample 5032 (1) and a fresh Fe-oxide spring deposit, 1202 (2). Sample 5032 contains 457 ppm Pb and 1202 contains 153 ppm Pb.

along the creek. Values are higher in the sediment from streams draining the east side of the valley.

7. Rock geochemistry

Iron oxide-spring samples from the east side of the creek have elevated As, Cd, Sb, Ni, Co, Mn, U and Zn similar to those found by Carne, 1983. Some of the samples also have up to 153 ppm Pb and 155 ppb Hg. Sequential extraction analysis shows that 0.25 M NH₂OH HCl extracts much of the Mn and Co from both Fe oxide spring deposits and ferricrete suggesting that Mn-oxides adsorb Co and that the maturity of the deposit has little effect on the absorption ability of the Mn oxide (Figure 11). More of the Fe, Ni, Zn and Pb are liberated by 1M NH₂OH HCl and HF-HClO₄-HCl-HNO₃ acids and the association of metals in the Fe-oxide spring deposits is different than in the ferricrete. The difference suggests that, as the Fe-oxide deposit matures to ferricrete, the metals become more strongly bound and more likely to be transported by mechanical rather than hydromorphic dispersion.

GUIDES TO GEOCHEMICAL DATA INTERPRETATION

Formation of geochemical anomalies in different surficial media (e.g. till, soil, stream sediment, lake sediment, water, vegetation) depends on interrelated factors such as size and type of bedrock mineralization, ice-flow direction, thickness and type of glacial deposit, topography, drainage, climate, vegetation and the geochemical mobility of elements. There are numerous possible combinations of these variables producing anomalies with many different variations of size and contrast. Models can simplify this complexity by displaying the geochemical anomaly pattern that can be anticipated for a specific combination of key variables such as till thickness and drainage. Element variations are most commonly displayed on maps by different size symbols or by contours. Therefore, the three dimensional models showing an expected anomaly pattern are linked to idealized two dimensional symbol maps. An example of a model and the expected geochemical symbol map for a survey carried out in a high relief area where there is a single mineralized bedrock source covered by colluvium is shown in Figure 12. Three potential sources for a stream sediment anomaly are shown in the Figure. Sulphides from the mineralization and metal-rich spring sediments are transported by gravity into the stream at A and B. Metals also enter the stream in ground water from a mineralized seepage at C.

Models can help simplify multi-media geochemical data interpretation by

more clearly showing the relationship between bedrock and surficial geochemistry and identifying geochemical pathfinders for sedex type mineralization. They can also be used to better define such geochemical exploration guidelines as optimum sample density, sample media and pathfinder element suites for different types of mineral deposit. A summary of the geochemical characteristics for sedex type Pb-Zn-Zn-Ba deposits is shown in Table 2.

Table 2. Geochemical summary

Media	Pathfinders	Anomaly Size	Remarks
Rock	Ag, Ba, Cd, Hg, Pb, Mn, Tl, Se, Ba	Unknown	Ba and Mn may form haloes around sulphides.
B Soil horizon /glacial sediment	Ag, Ba (INAA), Pb, Hg, Zn	100 m x 1000 m Pb BG = 200 ppm Zn BG = 1000 ppm. Pb contrast can be 50-60.	Little displacement of Pb-Ba-Ag anomalies from mineralization. Zn anomalies show large displacement.
Sediment	Pb, Ag, Ba, Cd, Hg	Zn-Zn-Ba anomalies can persist 2-3 km downstream from mineralization.	Pb-Ba levels generally higher in moss compared to sediment. Other elements show little difference.
Spring-stream water	Low pH, Al, Pb, Tl, Ba.	Elevated values decay to background within 100 m from acid spring.	Elevated As, Ca, Co, Ni, Mo, U, V, Zn indicates ground water from thrusts in pyritic shale. SO ₄ not specific to sedex deposits.
Fe-oxide spring deposits	Pb-Ag	May cover several Km ² in area. May be several m thick.	High Pb-Tl-Hg indicate sedex source. Elevated As, Co, Ni, Mo, U, V, Zn caused by adsorption from ground water by Fe oxides. Co typically associated with Mn oxides.

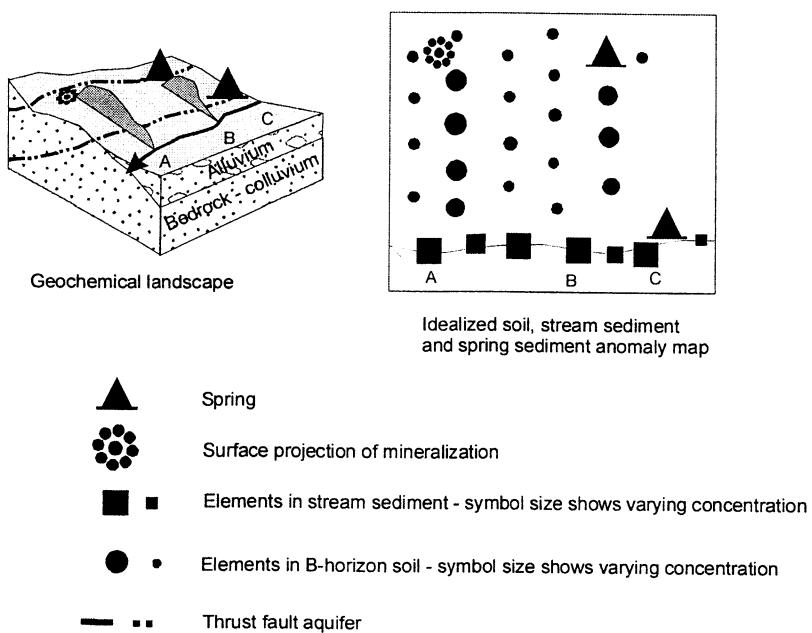

Figure 12. Geochemical model and idealized anomaly map for spring geochemistry

PART 2

GEOCHEMICAL RESULTS

Part 2 of Open File 2001-07 describes the results of detailed spring sediment, soil, till and spring water geochemical studies carried out in the Driftpile Creek area in 1994 by the British Columbia Geological Survey to study these problems. It consists of the following sections:

- Location, regional geology and geochemical signature of sedex mineralization
- Surficial sediments and spring related deposits
- Sampling and field methods
- Sample analysis and quality control
- Summary statistics for stream and moss mat sediments, spring and stream water, soil and rock samples
- Location, surficial geology, local geology, mineralization and geochemical results for each area.
- Summary of results
- Sample location and selected element symbol maps
- Listings of field variables, analytical and quality control data (Appendix A, B, C, D, E, F)

Analytical and field data are included as an ASCII file on a 3.5-inch high-density diskette located in the back pocket of the Open File.

Table 1. Summary of mineralization, surficial deposits and environment for detailed study areas.

Area	Mineralization	Surficial Deposits	Surface environment -soils
Bear	Massive and laminated pyrite, galena, sphalerite and barite. Ferricrete and iron oxide spring deposits.	Felsenmeer, talus, colluvium, glacial sediments. 20-30% bedrock exposure.	Steep and inclined topography, Boreal forest, Sombric brunisol and organic soils. Limited surface exposure of mineralization.
North Bear	Traces of barite, pyrite, galena and sphalerite. Ferricrete and iron oxide spring deposits.	Felsenmeer, talus, colluvium, till and fluvio-glacial deposits. 20-30% bedrock exposure.	Steep and inclined topography, Boreal forest, Sombric brunisol and organic soils.
Spar	Traces of pyrite, hydrozincite and barite. Large ferricrete and iron oxide spring deposits.	Felsenmeer, talus, colluvium, till and fluvio-glacial deposits. 10-20% bedrock exposure.	Steep, rolling and inclined topography, Boreal forest, Sombric brunisol.
Driftpile	Massive and laminated pyrite, galena sphalerite and barite. Ferricrete, gossan and iron oxide spring deposits.	Felsenmeer, talus, colluvium, till, fluvio-glacial and alluvial deposits. 10-20% bedrock exposure.	Steep and rolling topography, Boreal forest, Sombric brunisol and organic soil. Limited surface exposure of mineralization. Extensive surface disturbance due to trenching and road building.
Saint	Traces of barite, pyrite, galena and sphalerite. Ferricrete and iron oxide spring deposits.	Felsenmeer, talus, colluvium, till, fluvio-glacial and alluvial deposits. 10-20% bedrock exposure.	Steep and inclined topography, Boreal forest, Sombric brunisol and organic soils. Limited surface exposure of mineralization.

SURVEY AREA DESCRIPTIONS

Five sites neighbouring Driftpile Creek were selected for detailed geochemical sampling and study. Characteristics are summarized in Table 1. The region, situated east of the Rocky Mountain Trench in the Muskwa Range of the northern Rocky Mountains is characterized by northwest-trending mountain ridges which are 1000 metres to over 2000 metres in elevation. Evidence of alpine glaciation can be found throughout the area. The rugged topography reflects rapid physical erosion of the Palaeozoic sedimentary rocks. Streams flow in a predominantly trellised drainage pattern. Steep sided, narrow northwest-trending valleys are intersected by larger, subsequent, east to west-trending valleys. The tree line reaches up to 1500 metres with mixed woodland and grassland in the valley bottoms and alpine fir, black spruce and alder extending up the valley sides. Surface flora above 1500 metres consists of scattered alpine fir, willow and heather. Irregular patches of soil, covered by Fe-oxide crusts, are common throughout the area. Many of these non-vegetated 'kill zones' are associated with active springs and seepages; others reflect high levels of elements such as Pb, Ba, Zn and Ag in the Fe-oxide deposits.

REGIONAL GEOLOGY

The geology, mineralization and structure of the Driftpile Creek area have been previously described by Carne (1983), McClay and Insley (1985) and MacIntyre, (1992) and by Ferri *et al.* (1995). Bedrock geology consists of a

northwest-trending belt of tightly folded, predominantly black, fine-grained siliciclastic Paleozoic rocks typical of euxinic basinal sediments. Locally, the oldest rocks are Ordovician carbonaceous black argillites, cherts and thin limestone beds succeeded by Silurian orange-weathering dolomitic micaceous siltstone. The siltstone is overlain by lower Devonian recessive silver-grey weathering black argillite, chert and, locally, crinoidal limestone. These strata form the Road River Group.

Above the Road River Group is a conformable sequence of Middle to Upper Devonian laminated siltstone grading up into recessive, silver-weathering black argillites, cherty argillite, thin-bedded chert and, locally, chert-pebble conglomerate. These rocks form the Gunsteel formation of lower Earn Group in the Gataga district. The Gunsteel formation hosts several stratiform barite-pyrite-galena-sphalerite deposits such as the Bear and Driftpile Creek. The geological structure of the Gataga District is dominated by northwest-striking, steeply dipping chevron folds and west-dipping thrusts such as the Mount Waldemar thrust. This structure separates the Road River Group in the west from the lower Earn Group rocks in the east.

GEOCHEMICAL SIGNATURE OF MINERALIZATION

Sedex sulphide deposits in the Gataga district consist of sphalerite, galena, pyrite, pyrrhotite and rare chalcopyrite with or without barite (MacIntyre, 1995). Sedimentation and sulphide deposition demonstrate a rhythmic pattern characterized by pyrite-

laminated siliceous argillite at the base of the sequence succeeded by laminated pyrite-sphalerite-galena; massive barite and carbonate nodules and blebby barite at the top (Nelson *et al.*, 1995). Sedex sulphide mineralization typically has a distinct geochemical signature. Deposits are typically zoned with high Pb close to an exhalative vent and increasing Zn levels outward and upward from the vent. High Cu is usually associated with the vent feeder zone. Barite, exhalative chert and hematite-chert iron formation, if present, are usually found as a distal facies to the vent. Sediments such as pelagic limestone interbedded with the ore zone may be enriched in Mn. Some deposits are known to have NH₄, Zn, Pb, Cd, Hg and Mn haloes. Regionally, the sedex host rocks can be Ba-rich.

SURFICIAL DEPOSITS

Glaciogenic landforms typical of the region around Driftpile Creek include long, U-shaped valleys, hanging side valleys and proglacial lake strandlines. Air photos indicate that ice flow through major valleys was, most likely, topographically controlled. This interpretation is based on the presence of numerous, sharp, arêtes and horns that occur in the cirque valleys above the South Gataga River valley. These peaks may not have been completely ice-covered during the last continental glaciation.

Ice flow through the South Gataga River valley was, most likely, to the southeast based on streamlined landforms. However there are large lateral (and medial) moraines that begin in smaller cirque valleys and extend and bend to the southeast when they reach

the Gataga valley. In order for this to occur, ice must be flowing to the southeast in the Gataga valley.

A prominent terrace at the 1350-metre elevation along both sides of Driftpile Creek marks a transition from the steeper valley side to the more subdued upland topography. The terrace consists of sandy textured deposits. Well-sorted, gravel-textured deposits also occur at the 1600-metre elevation on a steep, south-facing hill slope close to the Bear occurrence and could be moraine or proglacial lakeshore sediment. Irregular mounds and short ridges cover the floor of a valley south of Driftpile Creek. These features may represent ice melt-out sediments.

Valley floor and lower hill slopes are mantled by an unknown thickness of till and colluvium. Above tree line, ridge crests and steeper hill slopes are covered with rock talus and felsenmeier. A typical soil catena consists of regosols, alpine dystric brunisols above tree line, orthic dystric brunisols on moderate hill slopes, gleysols and organic soils along the margins of streams.

SPRING-RELATED DEPOSITS

A variety of spring deposits occur in the Gataga District. The most common are:

- Small (10-20 cm high) mounds surrounding the actual spring discharge. The 'cold-spring' mounds consist of laminated red to dark brown Fe-oxide terracettes.
- Laminated, Fe-oxide surface crusts that are probably derived from the physical erosion of the cold spring deposits. The surface crusts also

consist of variegated, friable Fe-oxide sinter that can form slabs scattered over the surface of vegetation kill zones. In the Red Gossan area Fe-oxide sinter is associated with kill zones of 1 square kilometre in size, with no related groundwater discharge.

- Ferricrete deposits consisting of rounded Paleozoic pebbles and cobbles cemented with sandy textured ferruginous material. These deposits may be several metres thick and can extend for several hundred metres along the side of creeks. No active springs are associated with the deposits.
- White-coloured, laminated precipitate coating clastic sediment and vegetation debris in stream channels. This type of precipitate is less common than the ferruginous deposits and is most likely to consist of aluminium hydroxide or secondary barite. The precipitate is not generally found in surrounding springs, but is most evident in the channel several metres downstream from the discharge. White precipitates occur in streams draining the Bear occurrence and the streams draining into the north Bear valley.
- White-coloured, laminated travertine and calcrete. This type of deposit is found locally forming the bank of a small pool surrounding a spring in the upper reaches of Crude Creek.

SAMPLING AND FIELD METHODS

Geochemical samples were collected around the five areas by helicopter supported ground traverses:

- Bear Property area

- North of the Bear Property
- Red Gossan zone area
- Driftpile Creek deposit-Crude Creek
- Saint Creek

Samples of the following media were collected:

1. Water from seeps, springs and surface streams. Water pH and temperature were measured at the sample site with a Corning Checkmate meter. Dissolved solids (conductivity) were measured with a Hanna Model 3ATC meter and dissolved oxygen using a Hanna 8543 oxymeter. Sufficient water was collected to prepare a filtered (0.45 um), acidified (ultrapure nitric acid to pH 2) sample and a non-acidified sample in the field laboratory. Sulphate and alkalinity were also measured in a field laboratory within 24 hours of collection with Hach analytical kits.
2. Spring precipitate and ferruginous sinter. Sample structure, texture and sample colour were recorded at each site. These samples were treated as soil or sediment if the material was soft and easily crushed.
3. Soil and surficial sediment from the area immediately surrounding some of the spring deposits and from sites along two detailed traverses crossing the sulphide-barite mineralized zone at the Bear Property. Sample structure, texture and sample colour were recorded at each site.
4. Rock and ferricrete. The ferricrete represented mature, hard Fe-oxide deposits or the matrix from rock clasts cemented with Fe-oxide.
5. Sediment and moss-mat samples from first and second order streams

at 250 metre intervals. The samples were taken to compare the geochemical expression of the sulphide mineralization in conventional and moss mat sediment. Sample texture, colour and other field data were recorded at each site.

SAMPLE ANALYSIS AND QUALITY CONTROL

The analytical methods used in this study include instrumental neutron activation (INAA) and acid digestion followed by inductively coupled emission spectroscopy (ICP-ES) for soil, sediment and rock, inductively coupled mass spectroscopy (ICP-MS) for waters and sequential extraction analysis of metals from rock and soil samples. These methods are described in more detail below.

Geochemical data interpretation relies on separating real geochemical trends caused by natural geological or environmental processes, from data fluctuations introduced by sampling and/or sample analysis. These fluctuations are measured in terms of accuracy (i.e. the difference between a measured value for an element and that reported in a standard reference material) and precision (i.e. difference between random duplicate analyses) from data generated by the routine analysis of reference standards and duplicate samples. The quality control scheme used to monitor the data reported in this Open File is based on inserting reference standards and duplicates into a batch of 20 samples collected and analysed. Each batch contains seventeen routine

samples, a field duplicate sample collected adjacent to one of the routine samples, a blind duplicate sample split from one of the 17 routine samples prior to analysis and a control reference standard containing material of known element concentrations (either Canada Centre for Mineral and Energy Technology certified standard or a Geological Survey Branch 'prepared' bulk sediment sample). The locations of blind duplicate and control reference samples are selected before sampling, whereas field duplicate sites are chosen randomly during fieldwork. Blind duplicate samples have not been used in the quality control scheme for water sample analysis.

WATER

Filtered, acidified water samples were analysed for 66 elements by inductively coupled plasma mass spectroscopy and inductively coupled plasma emission spectroscopy (Perkin Elmer Elan 6000 mass spectrometer) at Activation Laboratories Ltd., Ancaster, Ontario. Several of the elements determined are not reported because of known inter-element interference (Ti) and the probable post-sampling decay of element concentrations (Hg, Au, Pt). The water data quality was monitored by the results of filtered, acidified distilled water blanks, blind sample replicates and standards prepared by spiking bulk-filtered water from Crude and Driftpile Creeks with Cd, Cu, As, Co, Ni and Zn. Sulphate and F were measured by ion chromatography-specific ion electrode by Chemex Laboratories, Vancouver. Instrumental detection limits (IDL) and method detection limits (MDL) for each element are listed in Table 2. The method detection limit is calculated at

the mean + 3 standard deviation concentration from data for the ultrapure nitric acid filtered, acidified, distilled, deionized water blanks inserted into sample batches before routine analysis. The method detection limit indicates contamination caused by field-based sample filtration. Analytical precision is estimated from percent relative standard

deviation values calculated from repeated analyses of the GSB Driftpile and Crude Creek water standards. Percent relative standard deviation values for elements including Ba, Pb, Cu, As, Co, Ni, Zn and Cd are listed in Table 2. The relative standard deviation at concentrations above 10x IDL is typically less than 5 percent.

Table 2. Detection limits and analytical precision for water analysis.

**SPRING DEPOSIT, SOIL, STREAM
SEDIMENT AND MOSS MAT
SEDIMENT**

Spring deposit and soil and samples were air dried and sieved to - 230 mesh (<0.063 mm) size. Stream sediment and moss mat samples were air dried and sieved to - 80 mesh (<0.180 mm) size. Both size fractions were analysed by Acme Analytical (Vancouver) for 29 elements (Mo, Cu, Pb, Zn, Ag, Ni, Co, Mn, Fe, As, U, Th, Sr, Cd, Sb, Bi, V, Ca, P, La, Cr, Mg, Ba, Ti, B, Al, Na, K and W) by aqua regia digestion and inductively coupled plasma emission spectroscopy (ICPES). Mercury was analysed by cold vapour atomic absorption spectrometry. Thirty-five additional elements (Au, Ag, As, Ba, Br, Ca, Co, Cr, Cs, Fe, Hf, Hg, Ir, Mo, Na, Ni, Rb, Sb, Sc, Se, Sn, Sr, Ta, Th, U, W, Zn, La, Ce, Nd, Sm, Eu, Tb, Yb and Lu) were determined by thermal instrumental neutron activation analysis (INAA) by Activation Laboratories, Ancaster, Ontario. Neutron activation is non-destructive to the sample and provides a "total" estimate of an element concentration. It cannot, however, measure elements such as Pb and Cu.

These can be determined on a separate sample by an aqua regia digestion and ICPES. An aqua regia digestion, while very effective for dissolving Au, carbonates and sulphides, cannot completely break down aluminosilicate, oxide and other refractory minerals such as barite. Consequently, element concentrations determined by aqua regia-ICPES are "partial" rather than "total". Detection limits for elements determined by INAA and aqua regia-ICPES are listed in Table 3. Percent relative standard deviation (mean/standard deviation) calculated from duplicate analyses of a GSB standard and the USGS rock standard GXR 1 is also shown in Table 3 with the recommended values for standard (Glasney and Roelandts, 1988).

Precision (%RSD) for massive sulphide indicator elements (e.g. Ag, As, Au, Ni, Cd, Co, Pb, Zn) is typically below 10 percent at concentrations above 10x IDL. The percentage difference between values for the blind duplicate field and analytical samples for elements such as Pb, Zn and Ag is typically below 15 percent.

Table 3. Detection limits and precision for soils analysed by INAA⁽¹⁾ and aqua regia-ICPES⁽²⁾

FERRICRETE AND ROCK SAMPLES

Ferricrete samples were broken up in a ceramic mortar and crushed material sieved to - 80 mesh (0.180 mm). Rock samples were crushed and ground in a tungsten carbide mill to - 150 mesh (0.075 mm). The sieved/milled samples were analysed for 34 elements (Mo, Cu, Pb, Zn, Ag, Ni, Co, Mn, Fe, As, U, Th, Sr, Cd, Sb, Bi, V, Ca, P, La, Cr, Mg, Ba, Ti, Al, Na, K, W, Zr, Sn, Y, Nb, Be, Sc) by hydrofluoric-nitric-perchloric-hydrochloric (HF-HNO₃-HClO₄-HCl) acid digestion - ICPES and for 32 elements by INAA. Mercury was analysed by cold vapour atomic absorption spectrometry. Detection limits for elements determined by INAA and hydrofluoric-nitric-perchloric-hydrochloric acid ICPES are listed in Table 4 with precision (% relative standard deviation) from duplicate analyses of USGS standard GXR-1.

SEQUENTIAL EXTRACTION ANALYSIS

Elements in selected iron oxide-spring deposit, rock and soil samples

were determined by a sequential extraction analysis at XRAL Laboratories, Toronto. One gram of the sieved or milled sample was extracted with 0.25M-hydroxylamine hydrochloride (NH₂OH HCl) for 2 hours at 60°C. The residue from the 0.25M NH₂OH HCl extracted with 1 M NH₂OH HCl - acetic acid for 3 hours at 90°C and the residue from this extraction then digested in concentrated HF-HNO₃-HClO₄-HCl acids for 1 hour at 90°C. The extracts were analysed for V, Mn, Co, Ni, Cu, Zn, As, Mo, Ag, Cd, Sb, Ba, Tl and Pb by ICPES. Detection limits for elements determined in the three extractions and the precision (expressed as % relative standard deviation based on repeated analysis of USGS standard GXR-1) are listed in Table 5. The precision for Ag, Cu, Mn, Pb, V and Zn in all extractions is better than 10 per cent. Poorer precision for other elements reflects low concentration in specific extractions or, in the case of Sb-3, an isolated low value for one determination of GXR-1.

Table 4. Detection limits and precision (GXR-1) for rocks analysed by INAA⁽¹⁾ HF ICPES⁽²⁾

SUMMARY STATISTICS

Mean, median and percentile values, calculated from soil, spring deposit, rock and water data for all of the survey areas, are listed in Tables 6 through 13. Data for each sample type (e.g. rock, water) has been subdivided according to the two main contrasting media represented. For example, stream sediment data has been subdivided into sediment or moss mat sediment data, water into stream or spring-seep water data, soil into Fe-rich oxide or Fe-poor samples and rock into Fe-rich or Fe-poor sediment.

The mean, median and maximum concentrations of most elements are higher in moss mat sediment samples (Table 6) compared to conventional stream sediments (Table 7). The

differences are greatest for Au, Ba, and Pb that are most likely to be transported and concentrated as heavy mineral grains. Most geochemically mobile elements such as As, Cd, Co, Cu, Hg, Ni, Mo, U and Zn are much higher in Fe-rich samples (Table 8) compared to the Fe-poor (predominantly shale) samples (Table 9). However, Au and Ba are higher in Fe-poor material because there are barite-rich and quartz-vein Au-rich samples from the North Bear area in the data set. Aluminium, As, Cd, Co, Fe, K, Mn, Ni and Zn are higher in spring waters (Table 10) whereas Ba, Ca, Mg and Pb are higher in stream waters (Table 11). Cobalt, Cu, Fe, Mo, Ni, U and Zn are higher in Fe-rich soils typically associated with Fe oxide-spring deposits (Table 12) whereas Ag, As, Au, Ba, Cd, Hg, Pb, Sb and Se are higher in soil, till and colluvium (Table 13).

Table 6. Moss mat sediment statistics. (1) = INAA (2) = Aqua regia-ICPES

RESULTS

1. MAIN BEAR AREA

Location: NTS 094F/13E; Latitude/Longitude: 57° 57' 46" N 125° 47' 08" W. MINFILE 94F024. Soil, rock and spring water samples were collected around the Bear sulphide occurrence. Stream sediment and water samples were also taken along the east branch and west branches of Bear Creek (local names).

Topography and surface environment

The Bear occurrence is located at an elevation of 1600 metres on a southeast facing hill slope. The only surface expression of the sulphide mineralization is a non-vegetated, barite covered "kill zone". There are also scattered, weathered sulphide showings along creeks and numerous Fe oxide spring and ferricrete deposits close to the headwaters of Bear Creek. Above tree-line (1500 metres) outcrop is almost continuous or covered by felsenmeier and talus fans. At lower elevations colluvium and/or glacial sediments cover bedrock.

Local geology and mineralization

Evans, 1995, has described the geology of the Bear massive sulphide occurrence. A thick sequence of unmetamorphosed upper Devonian Gunsteel Formation (Earn Group) black shales, siltstones, mudstones and turbidites strike northwest and, structurally, have been influenced by northeast directed folding and thrusting. The Gunsteel Formation is bounded to the west by the Waldemar thrust, which juxtaposes lower Devonian age chert-

pebble conglomerate of the Besa River Formation with the Gunsteel Formation. The sulphide-barite mineralization occurs towards the base of the Gunsteel Formation.

Sulphide mineralization has been traced by diamond drilling for more than 600 metres along strike and has been intersected over 200 metres below the surface. The mineralized zone in the Gunsteel Formation consists of basal cherts and graphitic shales containing pyrite laminations with disseminated galena and sphalerite. Massive barite and pyrite overlay the mineralized zone and are succeeded by siliceous shale containing laminated pyrite, carbonate and barite. At the top of the sequence is black shale containing carbonate, barite and pyrite nodules that grade into well-laminated turbidites. Grades of 1.6 gram/tonne Ag, 5.28 percent Zn and 0.11 percent Pb, over 6.0 metres have been reported by Evans, 1995, in the massive sulphides.

Results

A stream sediment survey (1 sample/100 metres) by Archer, Cathro and Associates in 1982 revealed that Pb decreased rapidly from one percent near the sulphide mineralization to a point 800 metres downstream where the sediment contained 200-300 ppm. The pattern of Ag variation in sediment was similar to Pb and the highest Ag concentration near the mineralization was greater than 10 ppm. Zinc was above 1000 ppm over an interval of 2.3 kilometres. Zinc threshold in stream sediments was determined at 500 ppm (Carne, 1983). A soil survey over the area underlain by the sulphide

mineralization outlined a northwest trending Pb anomaly up to 500 metres long and 100 metres wide with values above a 175 ppm threshold and up to 4000 ppm Pb. The peak of Pb anomaly was only displaced a small distance from the surface projection of the sulphide mineralization. Zinc soil anomalies above a 700 ppm threshold and up to 3000 ppm were displaced several hundred metres down slope. The distribution of Ag above a 0.6 ppm threshold was similar to Pb. (Carne, 1983).

Rock and water locations samples taken during the present detailed studies are shown on Map 1. Stream sediment locations are shown on Map 2 and soil sample locations on Map 3. Arsenic, Sb, Ba, Co, Cr, Mo, Ni, Pb, V and Zn are highly elevated in Fe-rich spring sediment, ferricrete and soil samples. Elevated Ba (> 74940 ppm by INAA), Pb (>1388 ppm), and Ag (> 2.1 ppm) occur in the B and C soil horizons over a 300 metre interval across the projected surface extension of the massive sulphide body (Maps 4 to 6). The B-horizon soil samples also have up to 9050 ppb Hg, 13 ppm Se, 14 ppm Sb, but Zn values less than 400 ppm (Map 7). The difference between the Pb and Zn B-horizon soil geochemistry most likely reflects higher Zn mobility in the acid soil caused by oxidizing pyrite. Aqua regia-ICP Ba values less than 100 ppm compare to INAA Ba levels in soil up to 28,000 ppm. The difference between the aqua regia-ICP Ba and INAA Ba in the B-horizon can be explained by the high concentration of refractory barite in the soil close to sulphide-barite mineralization.

Up to 37,000 ppm Ba in rock (Map 8) occurs in the matrix of a ferricrete outcrop on Bear Creek (west branch). This sample also has 1256 ppm Pb (Map 9), 2500 ppb Hg, 3 ppm Ag (Map 10), but less than 300 ppm Zn (Map 11). The Ba-Pb anomaly could reflect metals precipitated from acid ground water solution at high pH and adsorbed by the Fe-oxide. A sample of recently formed, laminated Fe-oxide by a spring on the east branch of the creek only has 2800 ppm Ba, but over 10,000 ppm Pb and 32 ppm Ag (sample 945017 on Map 1). Again, precipitation of PbSO₄ from mineralized spring water is the most likely source for the metal enrichment.

Barium (INAA) levels in stream sediment (Map 12) reach 15000 ppm close to the Bear Creek (east branch) headwaters. Values fall to 13,000 ppm below the confluence of the two branches of the creek (sample site 947022). The sediments have aqua regia-ICPES Ba values below 800 ppm suggesting that barite is present in the sediment. Mean and median Ba values are also higher in moss mat sediment, supporting the presence of barite. Sediment Pb (Map 13) and Ag (Map 14) are highest close to the source of the creek. Moss mat sediment Pb close to the source of Bear Creek east branch (947006) is 4949 ppm; Ag is 73 ppm. Lead decreases downstream, but remains above 200 ppm over a 3 kilometre reach of Bear Creek. Mean and medium Ag and Pb in moss mat sediment are much higher than in stream sediments.

Increasing Zn (Map 15) in sediment downstream from mineralization reflects decreasing Zn mobility with increasing water pH. Spring water draining into the

upper part of the Bear Creek has a pH below 5 (Map 21) and contains up to 392 ppb Pb (Map 17), 2.73 ppb Tl (Map 20),

over 6535 ppb Zn (Map 19) and 119 ppm SO₄.

Table 14. Metals extracted by 0.25M NH₂OH HCl,(e.g. Ag-1) 1 M NH₂OH HCl (e.g. Ag-2) and HF-HClO₄-HCl-HNO₃ (e.g. Ag-3) from a recent Fe-spring sediment (945017) mature ferricrete (945018, 945024)

Another spring of acid water (pH 3.85) flowing into the lower part of Bear Creek (west branch) has over 1100 ppb Al (Map 18) and 164 ppb Ba (Map 16).

A white precipitate coats the sediment around this acid spring.

Metal concentrations and percentages of the total metal extracted by 0.25M NH₂OH HCl, 1 M NH₂OH HCl - acetic acid and concentrated HF-HClO₄-HCl-HNO₃ from a recently formed Fe oxide-spring sediment sample and a mature ferricrete deposit sample are listed in Table 14.

More of the total Fe, Zn and Co is dissolved by 1M NH₂OH HCl from recent Fe-oxide spring deposit (sample 945017) than from a mature ferricrete deposit (sample 945024). However, more Fe is extracted from ferricrete by HF-HClO₄-HNO₃-HCl acids compared to 1M NH₂OH HCl. More Zn Co and Mn are also released by the 0.25M and 1M NH₂OH HCl from the Fe-oxide spring deposit compared to the ferricrete suggesting that, as the deposit matures, metals become associated with the most resistant minerals. A higher proportion of Pb and Ag are extracted by 1 M NH₂OH HCl from the recently formed Fe-oxide spring deposit compared to amounts dissolved from ferricrete. This suggests that Pb is more mobile in the early stages of deposit formation and may be relatively weakly bound to the oxide surface or precipitated as Pb sulphate.

2. NORTH BEAR AREA

Location: NTS 094K/4 and 094K/13; Latitude/Longitude: 58° 00' 00" N 125° 49' 00" W. Soil, rock and spring water samples were collected along a valley extending north from the Bear occurrence.

Topography and surface environment

The North Bear area is a U shaped valley one kilometre north of the Bear

occurrence. Numerous Fe oxide spring and ferricrete deposits are scattered along both sides of the valley. Above tree-line (1500 metres) outcrop is almost continuous or covered by felsenmeer and talus fans. At lower elevations bedrock is covered with colluvium or till that was most likely deposited by ice advancing parallel to the valley axis. Alluvium and glacio-fluvial deposits are also present on the valley floor. Several of the first-order streams draining into the main creek have a thick, white precipitate coating boulders and bottom sediments.

Local geology and mineralization

Rocks of the Gunsteel and Besa River Formations extend into the North Bear valley from the Bear occurrence. Rock types include non-siliceous, thick-bedded gritty black shale, a medium to thick bedded, siliceous and non-siliceous shale and a cherty black argillite containing blebby barite and traces of pyrite, galena and sphalerite. The Gunsteel Formation is in thrust contact with silty black shale and conglomerate of the Besa River Formation to the west. The valley forms the axis of an overturned syncline and the contact between the Gunsteel and Besa River Formation is commonly a low-angled, west-dipping thrust fault. Ferricrete deposits are common along both sides of the valley around springs discharging from thrust faults.

The only reported sulphide mineralization in the North Bear valley is the Bob occurrence (MINFILE # 094K085) where barite-Pb-Zn-rich massive pyrite mineralization (0.38 % Zn) has been found by diamond drilling in tightly folded, thinly bedded black

shale, cherty argillite, and baritic-pyritic mudstone. This occurrence is north and downstream of the area covered by the sampling.

Results

Rock and water sample locations are shown on Map 22; stream sediment and soil sample locations on Map 23. The highest INAA Ba levels (>21000 ppm and up to 3.8 %) in rock samples are from the east side of the valley (Map 24). However, these samples have low Pb, Zn and Ag values falling in the 50 to 90 percentile range (Maps 25, 26, 27).

Iron-rich spring deposit and ferricrete samples in the North Bear area have high Ba, Pb, Ag and Zn levels (Maps 28-31) and are enriched in As, Sb, Co, Mo, Ni, and V. The highest Pb (2798 ppm) detected in the spring deposits is in sample 941043 close to the main creek on the east side of the valley. This sample also has 63 ppb Au. The spring water (943079) in contact with this sediment is weakly acid, and has elevated Fe, Sb and As levels. An outcrop of graphitic shale close to the mineralized spring contains 157 ppb Au (Map 36), 233 ppm Pb, 0.7 ppm Ag and 45 ppm Sb. Other acid springs (Map 32) on the east side of the valley have high Al (Map 33), Pb (Map 34) and Zn (Map 35). The source of high Au, Pb (Map 37), As (Map 38) and Ag (Map 39) in moss sediment for 2 kilometres in the main stream could be the Au-Pb enriched graphitic shale that has enhanced Au and Sb.

Different sources for ground water are demonstrated by the chemistry of two springs only metres apart on the east side of the valley (Area A). Sample 943086 is

acid (pH 4.44), oxygenated (DO 8.3 ppm) and has elevated Pb, Tl, Al, Co, Ni, Cd, Zn, and rare earth elements, but is low in Fe. Spring water sample 943087, however, is weakly alkaline (pH 7.2), oxygen depleted (DO 0.2 ppm), high in Fe and has non-detectable levels of rare earth elements. A thick Fe-oxide precipitate surrounds this spring. There is no sediment surrounding the adjacent acid spring (943086), but a thick Al-Fe precipitate coats sediment down-stream from the source at a point where the water pH becomes weakly alkaline.

3. RED GOSSAN (SPA SHOWING) AREA

Location: NTS 94K/13E;
Latitude/Longitude: 57° 57' 45" N, 125° 44' 00" W. MINFILE 94F 003. Samples were collected in the valley of a south flowing creek. Sampling focused on several large iron spring deposits on the west side of the valley.

Topography and surface environment

A large dry, surface Fe-oxide deposit (the Spa Mineral Showing) extends over several square kilometres at 1200 metres elevation on the west side of the valley. The creek in this valley flows south into Gataga lakes. There are several, smaller Fe-oxide deposits, each associated with an active spring, roughly two kilometres to the north. Glacial sediments are most likely till deposited on the gently-sloping valley side surrounding the dry Fe oxide-deposit. Vegetation consists of alpine fir, black spruce and alder at lower elevations and scattered alpine fir and willow above 1500 metres.

Local geology and mineralization

The most impressive surface feature of the Spa showing is a large area (350 by 100 metres) of dry Fe oxide sinter up to 6 metres thick that most likely reflects a past episode of Fe precipitation from ground water flowing from a west dipping thrust fault. The sinter is underlain by gritty black shale and siltstone of the Besa River formation (the eastern equivalent of the Earn Group). Sub-surface mineralization at the Spa showing consists of secondary zinc minerals (hydrozincite, melanterite) along fractures in the shale, barite beds, nodular barite and a thin (5 mm) barite-sphalerite-arkerite vein. Minor disseminated and laminated pyrite has also been reported (Somerville, 1980).

Results

Soil sampling and diamond drilling carried out by Archer, Cathro and Associates in 1980 detected percent levels of zinc in soil (Somerville, 1980).

Soil sample locations are shown on Map 40; rock and water sample locations on Map 41. The geochemistry of a soil profile below the area of dry sinter at the Spa showing is shown in Table 15. The surface deposit consists of loose, Fe-oxide cemented shale clasts (941108). Below this material is Fe-stained blocky clay containing up to 50 percent shale clasts (941109, 941110). Silver, Cd, Co, Fe, Hg, Mn, Ni, U and Zn are higher in the surface deposits sinter compared to

underlying clay-rich sediment whereas As, Ba, Cr, Cu, Mo, Sb and V increase down the profile. Results of soil geochemistry for the Spa and Area B (Maps 44 to 45) show the reported high Zn and Ba up to 6.4 percent in the sinter. Arsenic, Sb, Co, Cr, Ni, Mn, Hg, Mo, Ni, W, V and U typically exceed several hundred parts per million in the sinter. Rock samples from Fe-oxide deposits associated with the active springs north of the Spa showing (Area B) have similar concentrations of these metals. However, the highest Pb in the sinter and Fe spring deposits in Area B is only 23 ppm. The distribution of Ba, Pb, Ag, and Zn in rock samples from the Spa and Area B is shown in Maps 46 to 49.

Concentrations and percentages of metals extracted with 0.25M NH₂OH HCl, 1 M NH₂OH HCl and HF-HClO₄-HCl-HNO₃ acids from Spa profile samples 941108, 1109 and 1110 are listed in Table 16. In most of the samples more than 90 per cent of the total As, Ba, Mo and V is bound in the most resistant fraction (HF-HClO₄-HCl-HNO₃ extractable) suggesting that these metals

occur in shale or in mature “aged” Fe-oxide. More of the total Zn, Ag, Co and Ni is extracted by the 0.25 and 1.0 NH₂OH HCl₂ indicating that these metals were most likely concentrated by Fe-oxides from ground water when the Spa springs were active

Presently, the active springs near the Spa prospect are along the west side of the valley 2 kilometres to the north (Area B). The spring water pH is typically > 7

(Map 52), and has a high Ca, Mg, Sr, Fe and SO₄ content, but low dissolved O₂. The water has up to 466 ppb Ni, 91 ppb Cd, 21 ppb As, 4000 ppb Zn (Map 51) and 6.3 ppb Pb (Map 50).

Low Pb and elevated As, Co, Cr, U, V and Zn in the Spa oxide sinter suggest that the weathered shale is the main source of the metals rather than Pb-Zn sulphides.

4. DRIFTPILE CREEK-CRUDE CREEK AREA

Location: NTS 94K/04

Latitude/Longitude: 58° 03' 59" N, 125° 54' 35" W; MINFILE 94K066

Topography and surface environment

The Driftpile Creek barite-Pb-Zn deposit (MINFILE 94K066) is located near the headwaters of Driftpile Creek close to the western edge of the Muskwa Ranges. Driftpile Creek flows to the west through a winding U shaped valley into the Kechika River. Terraces and ridges at the 1350-metre elevation along both sides of the Driftpile Creek valley indicate proglacial lakeshore and fluvio-glacial sediments. The terraces mark a gradient change from steeper slopes close to the valley floor to a more subdued upland topography.

Sulphide mineralization is rarely visible at surface. However, there is one limonitic gossan capping an outcrop containing sulphides close to Driftpile Creek ("Discovery Zone"). This gossan has an associated barite "kill zone". In addition, several other "kill zones", iron-spring and ferricrete deposits occur along the Driftpile creek valley and also

close to the headwaters of Crude Creek, a tributary of Driftpile Creek.

Local geology and mineralization

The geology of the Driftpile deposit (MINFILE # 94K066) has been described by Nelson *et al.*, 1995. Massive sphalerite, galena and pyrite occur in blue-grey weathering, carbonaceous black shale and silty mudstone, cherty argillite and radiolarian chert of the Gunsteel Formation. The rocks are preserved in a broad, northwest-trending, tightly folded synclinorium that has been disrupted by moderately dipping, northeast verging, thrust faults. Gunsteel Formation clastic sediments are interbedded with barite and/or pyrite-enriched siliceous shale or cherty argillite. The barite is nodular, disseminated, intercalated as thin laminae, or present as massive, centimetre-scale beds. Pyrite is generally laminated in mudstone, or associated with barite, or present as carbonate concretions. The Gunsteel Formation is in contact with the underlying Ordovician to lower Devonian Road River Group within the hanging-wall of the Mount Waldemar thrust fault to the south west of Driftpile Creek.

The Driftpile deposit consists of at least two stratiform sulphide-carbonate and barite bodies. The lower or 'main' zone up to 70 metres thick is primarily a sulphide-carbonate facies interbedded by black graphitic shale or mudstone. Within the zone fine-grained, finely laminated or frambooidal pyrite is associated with irregular bands and concretions of calcite. Sphalerite and galena can occur with the pyrite, but are most abundant as a layer of fine-grained

massive sulphide near the base of the zone.

The 'upper' zone, 100 to 200 metres higher in the Gunsteel Formation, consists of barite-sulphide mineralization, in siliceous or non-siliceous mudstone with pyritic laminations. Barite occurs in massive beds or laminations, or in nodules. Pyrite is subordinate to barite, but may form massive layers, locally accompanied by abundant sphalerite and galena.

Previous diamond drilling has established that sulphide mineralization typically grading 10 per cent Zn and 1 per cent Pb extends down dip for at least 100 metres, can be traced over a strike length up to 3 kilometres and has a surface width of 1.5 kilometres. The most recent reserve estimate (lower mineralized sub-unit of the 'main zone') is 2.44 million tonnes averaging 11.9 per cent Zn and 3.1 per cent Pb.

The DR barite occurrence (MINFILE # 94K077) is 2.5 kilometres southeast of the Driftpile deposit on Crude creek. Mineralization consists of nodules and thin lenses of massive barite in blue-grey weathering black shale and siliceous argillite of the Gunsteel Formation.

Results

The Driftpile deposit was discovered in 1973 following a 1970 regional stream sediment geochemical survey carried out by Geophoto Consultants (Wise, 1974).

Spring deposit and stream sediment sample locations are shown on Map 54; rock and water sample locations on Map 53. The soil and rock sampling was designed to establish the geochemical signature of the Ag-Pb-Zn sulphide mineralization.

Soil and gossan material from two vertical profiles (samples 941430 to 941434) at the "Discovery Showing"

kill zone have up to 7900 ppm Pb, 6400 ppm Zn, 34,000 ppm Ba and 0.5 ppm Ag.

The geochemistry of a vertical profile on the "Discovery Showing" is shown in Table 17. Iron and Zn decrease sharply from elevated levels in the gossanous surface material to lower concentrations in the underlying mottled soil whereas

Pb, Hg and Ba are almost constant down the soil profile. Results of the sequential extraction analysis (Table 18) show that much of the Pb is bound in the 1 M NH₂OH HCl and HF-HClO₄-HCl-HNO₃ acid extractable fractions. Most of the

Zn, however, is bound in the 0.25 M NH₂OH HCl extractable fraction. The differences between the partitioning of Pb and Zn suggest that more resistant galena or Pb sulphate is still present in the spring deposit, but sphalerite has been largely oxidized to more soluble secondary Zn minerals. The distribution of Ba, Pb, Ag and Zn is shown in Maps 55 to 58).

Ferricrete rubble covers the surface of a large "kill zone" roughly 150 metres by 30 metres in area located on the north side of the Driftpile Creek valley two kilometers east of the "Discovery" gossan. This "kill zone" is most likely underlain by rocks of the Upper Road River group. Barium, Pb, Mn, V and Tl increase with depth down a vertical profile below the surface of the "kill zone" whereas Fe, and Zn decrease with depth. Results of sequential extraction analysis on samples from the profile (Table 19) show that the 0.25 M NH₂OH HCl extracts most of the Mn, Tl and Co, 1.0 M NH₂OH HCl removes much of the Pb; the HF-HClO₄-HCl acids largely extract V, Cu and Ba. Proportions of Zn and Fe liberated by the three reagents change with depth. In the surface ferricrete more of the Fe and Zn is bound by HF-HClO₄-HCl-HNO₃ extractable phase whereas in the underlying soil the 1.0 M NH₂OH HCl extracts more of the metals. This suggests that Mn oxides are responsible for scavenging Co and Tl from ground water whereas Fe oxides adsorb Zn and Pb. Barium and V are present in resistant soil-forming minerals and are less susceptible to solution by acid ground water.

Maps 59 to 62 show the distribution of pH, Zn, Al and Pb in spring and

seepage water samples. A ground water source for the metals is suggested by the chemistry of a water sample collected from the bottom of a profile pit at Area A (Sample 943062). This water is acid (pH 3.7), SO₄-rich (324 ppm) and contains 1697 ppb Al, 91 ppb Ni, and 23100 ppb Zn, 7.3 ppb Pb and 3.3 ppb Tl (Maps 59-62).

Ferricrete samples from a vertical profile near the headwaters of Crude Creek (Area B) located four kilometres east of the Driftpile deposit have up to 2 percent Zn, 1000 ppm Ni, 1000 ppm As, 100 ppm U, 100 ppm Co and 800 ppm Mo but less than 20 ppm Pb, 1 ppm Tl and 1 ppm Ag. Sequential extraction data (Table 20) shows that more than 75 percent of the Fe, As, Ba, Mo, Ni, Sb, V and Zn are bound in the HF-HClO₄-HCl-HNO₃ extractable fraction whereas more of the Mn (75-80%) is dissolved by 0.25 M NH₂OH HCl. Other metals (e.g. Co, Zn) do not appear to be associated with oxides dissolved by the 0.25 M NH₂OH HCl. Most metals (e.g. Ba, Fe, Ni, V, Zn) increase down the profile from the ferricrete into the underlying sediment. Arsenic and Ba, however, decrease with depth. Spring water close to the ferricrete deposits is alkaline and has elevated levels of Fe, Ni, Mn and Zn, but no detectable Pb or Tl.

The distribution of Ba, Ag, Pb and Zn in moss and stream sediment samples from streams draining into Driftpile creek is shown in Map 63-66. Most moss and stream sediments have more than 1000 ppm Zn. However, only streams within two kilometres of the Driftpile creek deposit have more than 100 ppm Pb and 1 ppm Ag.

Comparison between the geochemistry of stream sediment and moss mat sediment samples from streams draining Pb-Zn sulphide mineralized (e.g. Driftpile deposit area) and non-mineralized areas (e.g. Crude Creek) are shown in Table 21. Elements typically concentrated in the heavy mineral fraction (e.g. Ag, Au, W, Pb) are higher in moss mat sediment compared to the stream sediment. However, this

trend is not always consistent because Pb is higher in the sediment for the sample pair 947043 and 44. Other elements (e.g. As, Ni, Zn, Mn, Cd, Cu, Mo) are higher in the stream sediment compared to the moss mat sediment or show no obvious preference for sample type.

Table 19. Metals extracted with 0.25M NH₂OH HCl, (e.g. Ag-1) 1 M NH₂OH HCl (e.g. Ag-2) and HF-HClO₄-HCl-HNO₃ (Ag-3) from surface ferricrete samples (945048 and 49) and from profile soil samples (941408-1411) under a "kill zone" in Area A.

5. SAINT CREEK AREA

Location: NTS 094K04W.
Latitude/Longitude: 58° 07' 26" N, 125° 59' 07" W. Water, sediment and iron oxide spring deposit samples were collected along a valley west of Saint Creek (local name). The area was within the boundary of the Saint-Flaco mineral claims, a property staked by Archer and Cathro Associates in 1980.

Topography and surface environment

Iron-oxide spring deposits are located along the east side of a steep sided, narrow northwest-trending U shaped valley west of Saint Creek. The unnamed creek flows northwest through Braid Creek into the Kechika River. The valley sides are covered with talus and colluvium. Unsorted, coarse textured, glacial sediments fill the valley floor. The tree line reaches up to 1500 metres with mixed woodland and grassland in the valley bottom and alpine fir, black spruce and alder extending up the valley sides. Surface flora above 1500 metres consists of scattered alpine fir, willow and heather.

Local geology and mineralization

Rocks of the Gunsteel Formation underlie the area north of the creek. Lithologies range from bluish-grey weathering carbonaceous cherty argillite, siliceous shale and bedded chert, with subordinate mudstone, to siltstone and coarser siliciclastics. Nodular, laminated or massive lenticular barite occurs at a number of horizons known to host Pb-Zn-Ag sedex mineralization at Driftpile Creek. However, on the Saint-Flaco claims, the barite-bearing strata (8 to 45

metres thick) have up to 5 per cent disseminated or laminated pyrite traces of galena and sphalerite (Carne, 1982; Insley and McClay, 1986). The rocks are thrust faulted and tightly folded into a series of northeasterly-overturned anticlines and synclines resulting in repetition of the baritic horizons on the surface. The Gunsteel rocks generally strike northwest and dip moderately to steeply southwest. In the southwest corner of the claims, a thrust juxtaposes dolomitic siltstones of the Ordovician-Devonian Road River Group onto the Gunsteel Formation. The iron-oxide spring deposits have up to one per cent Zn, but are not associated with the baritic horizons.

Results

Soil and Fe-oxide spring deposit geochemical surveys by Carne, 1983, over the Saint-Flaco claims outlined Pb and Zn soil anomalies. Soil with Pb above 175 ppm covers an area roughly 1200 metres by 400 metres on the west side of the creek. Lead concentrations reach 6200 ppm and the peak on the Pb soil anomaly trends northwest. Zinc levels above 1000 ppm and up to 10,000 ppm in soil occur in an area 1200 metres by 100 metres parallel to the creek. The peak of the Zn soil anomaly appears to be centered on the creek. Geochemical analysis of the Fe-oxide spring deposits was aimed at distinguishing between "exotic" anomalies caused by adsorption of metals from ground water and metals derived from sulphides in the underlying bedrock. The Fe-oxide spring deposits were found to have varying enrichment in Pb, Zn, Mn, As, Mo, Co and Ni. Cobalt/Ni ratios in spring deposit samples were tested as a tool to

distinguish between pyrite formed with VMS mineralization and digenetic pyrite. The Co/Ni ratios for most samples were found to be less than 0.5. Higher ratios (> 0.5) were found in Fe-oxide spring deposits at the south end area close to the headwaters of the creek (Carne, 1983). A prominent source of metals in the Fe-oxide spring deposits was identified as ground water flowing from a thrust on the east side of the creek.

Soil and sediment sample locations are shown on Map 67; water and rock sample locations are shown on Map 68. Spring waters have a pH > 7 and have very high concentrations of Ca, Mg, Na, Fe, Co, Ni, Cd and Zn (Map 70). The most acid spring water (pH 6.4) found is at the south end of the area and drains into the headwaters of the creek (sample 943053). This water also has the elevated Ba (83 ppb) and Al (361 ppm), but less than 0.1 ppb Pb (Map 69).

Stream sediment and moss mat sediment geochemistry is shown in Table 22. At two sites along the creek (samples 947034/35, 947040/42) both moss mat and stream sediment were

collected. The results show that Pb and Ba are higher in moss mat sediment compared to the stream sediment. However, this trend is not followed by other elements. For example, Cd and Hg

are much higher in sediment sample 947035 than in moss sediment 947034. A low aqua regia-ICP Zn value (131 ppm) in this sediment compared to a much higher INAA Zn (1720 ppm) accompanying the elevated Cd and Hg (1860 ppb) suggests that there could be sphalerite present. There are significantly elevated levels of Pb, Ba, Ag and Zn in stream sediment and moss mat sediment over a 3 kilometre reach of the creek. Values are higher in the sediment from streams draining the east side of the valley (Maps 71-74).

Iron oxide-spring samples from the east side of the creek have elevated As, Cd, Sb, Ni, Co, Mn, U and Zn similar to those found by Carne, 1983. Some of the samples also have up to 153 ppm Pb and 155 ppb Hg. There is similar Pb enrichment of metals up to 457 ppm in ferricrete deposits from outcrops along the east side of the valley close to the south end of the valley.

Results of sequential extraction analysis for Fe-oxide spring and ferricrete samples are listed in Table 23. The 0.25 M NH₂OH HCl extracts much of the Mn, Co, Ni, Tl and Zn suggesting that Mn-oxides adsorb these metals. Most of the Ba, Fe and Pb is liberated by 1M NH₂OH HCl indicating an association of these elements with Fe oxide. Vanadium, Ba and Pb are also released by HF-HClO₄-HCl-HNO₃. The partitioning of the metals into the different phases varies from the Fe-oxide spring deposits to the ferricrete suggesting that as Fe-oxide spring deposits mature to ferricrete the metals become more strongly bound and would therefore be more likely to be

transported physically rather than chemically.

Table 23. Metals extracted by 0.25M NH₂OH HCl (e.g. Ag-1), 1 M NH₂OH HCl (Ag-2) and HF-HClO₄-HCl-HNO₃ (Ag-3) from ferricrete samples 945032,33,34 and iron spring sediments 941201-941206.

SUMMARY

- Elevated Pb, Ag, Ba, Se, Hg and Tl in soil and stream sediment are pathfinders for sedex type Pb-Zn-Ag mineralization at Driftpile Creek and at the Bear occurrence.
- Elevated Pb, Tl, Al and Ba in acid spring water reflect oxidation and solution of Fe, Pb and Zn sulphides by ground water.
- Elevated As, Ca, Co, Ni, Fe, U, V, Zn and SO₄ concentrations in neutral to alkaline spring water reflect weathering of shale and transport of ground water to the surface along thrust faults. Elevated As, Co, Ni, Mo, U and Zn in Fe-oxide spring deposits reflect adsorption of metals from the mineralized ground water.
- Manganese oxides mainly accumulate Co and Zn in Fe-oxide spring deposits whereas Fe-oxides accumulate more As, Ni, Mo, Pb and Tl. Vanadium and Ba are in the most resistant phase of secondary Fe-oxides.
- The source for the metals at the Spar (Red Gossan) occurrences appears to be pyrite-bearing Gunsteel sediments that have background Pb and Zn levels.
- Additional sedex mineralization may be present along the east side of the valley north of the Bear occurrence and west of Saint creek. There may also be gold mineralization in the North Bear valley.

ACKNOWLEDGEMENTS

Much of the fieldwork would not have been completed without invaluable assistance from Wayne Jackaman. Graeme Evans and Randy Farmer (Teck-Cominco Inc.) are thanked for their hospitality in allowing access to the Driftpile Creek camp and for generously sharing information on the Bear and Driftpile deposits. A review of the Open File by Gib McArthur, Exploration Services Manager, GSB, greatly improved the content. Preparation of preliminary maps by Lara Forbes is very much appreciated. Lastly, the author would especially like to thank Michael Dawson for his efforts in producing a final version of the maps and for carefully and patiently editing the text.

APPENDIX A - WATER SAMPLE DESCRIPTIONS AND ANALYTICAL DATA

Reference Guide to Field Observations

MAP	1:50 000 NTS Map Sheet Number	
ID	Sample ID Number	
UTMZ	UTM Zone	
UTME	UTM East Coordinate (NAD 83)	
UTMN	UTM North Coordinate (NAD 83)	
STN	Replicate Sample Status :	
	0 - Routine Sample	
	1 - 1st Field Duplicate	
	2 - 2nd Field Duplicate	
TYPE	Sample type	
	SP - Spring	SE - Seepage
	ST - Stream	
FLOW	Water flow	
	S - Slow	M - Medium
	F - Fast	
COMMENTS	Additional comment about sample

Notes:

DO = Dissolved oxygen

uS = Conductivity in microseimens

NM = Not measured

ND = Not determined

APPENDIX B - SOIL SAMPLE DESCRIPTIONS AND ANALYTICAL DATA

Reference Guide to Field Observations

MAP	1:50 000 NTS Map Sheet Number
ID	Sample ID Number
UTMZ	UTM Zone
UTME	UTM East Coordinate (NAD 83)
UTMN	UTM North Coordinate (NAD 83)
STN	Replicate Sample Status : 0 - Routine Sample 1 - 1st Field Duplicate 2 - 2nd Field Duplicate
MED	Sample type: C - C soil horizon B - B soil horizon BC - BC soil horizon PPT - Iron oxide deposit
PDEPTH	Profile depth in metres
DEPTH	Sample depth in metres
STRU	Structure: Lo - Loose B - Blocky M - Massive
TEXT	Sample texture: Per cent pebbles (> 2 mm), sand (2-0.05 mm) Silt-clay (< 0.05 mm)
COL	Sample colour: R - Red G - Grey Y Yellow B Brown O - Olive D - Dark M - Medium L - Light
REMARKS	Additional comment about sample
DATE	Day/month/year

METHOD CODE 1 - INAA: 2 - Acid digestion - ICPES

941016	Bear area Fe-oxide precipitate	22/06/94	-5	-0.1	1.33
941017	Bear area Fe-oxide precipitate	22/06/94	-5	0.9	0.87
941022	Bear area Mainly angular Fe-oxide grains	26/06/94	-5	-0.1	0.61
941023	Bear area. 80% angular pebbles coated with Fe-oxide.	26/06/94	-5	-0.1	0.84
941024	Bear area. Abundant fresh Fe-oxide surrounding spring.	26/06/94	-5	0.2	1.37
941025	North Bear area. 70% angular shale clasts with Fe-oxide pebbles.	03/07/94	-5	0.6	0.63
941026	North Bear area. 70% angular shale clasts with Fe-oxide pebbles.	03/07/94	-5	0.4	0.43
941027	North Bear area. 70-80% angular shale clasts with Fe-oxide pebbles.	03/07/94	-5	0.8	0.75
941028	North Bear area. 70-80% angular shale clasts with Fe-oxide pebbles.	03/07/94	-5	0.5	0.38
941029	North Bear area. Thick Fe-hydroxide precipitate.	03/07/94	-5	-0.1	0.54
941030	North bear area. Gelatinous - filamentous red coating on shale pebbles & moss.	03/07/94	-5	-0.1	0.02
941032	North bear area. Pit at top of Fe-oxide stain zone.	03/07/94	-5	1.7	0.27
941033	North bear area - Fe hydroxide precipitate.	03/07/94	-5	0.1	0.62
941034	North bear area - Fe hydroxide precipitate.	03/07/94	-5	0.5	0.12
941035	North Bear area. Fe oxide crusts from surface - 1 m below spring.	05/07/94	-5	-0.1	0.01
941036	Field Duplicate sample 941035	05/07/94	-5	-0.1	0.01
941037	North Bear area. White precipitate coating talus	05/07/94	-5	0.4	7.62
941038	North Bear area. Soil-talus sample.	05/07/94	-5	0.4	0.83
941039	North Bear area. Fe-oxide crusts from around seepage.	05/07/94	-5	-0.1	0.91
941040	North Bear area. Light brown to white banded cold-spring deposit.	05/07/94	-5	1.4	8.43
941042	North Bear area. Iron precipitate surrounding spring and coating float.	05/07/94	-5	-0.1	0.09
941044	North Bear area. Fresh Fe-hydroxide 1 m below spring.	05/07/94	-5	-0.1	0.07
941047	North Bear area. Iron oxide precipitate coating float.	05/07/94	11	-0.1	0.03
941048	Field Duplicate sample 941047.	05/07/94	-5	-0.1	0.02
941103	Spar area. Pebbles 5% sub-angular shale.	23/06/94	-5	0.9	1.15
941104	Spar area. Pebbles 5% sub-angular shale.	23/06/94	-5	0.4	0.55
941105	Spar area. Pebbles 10% sub-angular shale	23/06/94	-5	0.5	0.65
941106	Spar area. Pebbles 10% sub-angular shale and barite.	23/06/94	-5	1.7	1.44
941107	Spar area. Pebbles 20% increasing to 40% at pit bottom. Sub-rounded shale & Fe stained material.	23/06/94	-5	1.4	1.38
941108	Spar area. Pebbles 20% sub-angular shale and ferricrete.	23/06/94	-5	1.3	0.55
941109	Spar area. Pebbles 50% sub-rounded shale in blocky Fe stained clay.	23/06/94	-5	0.8	0.86
941110	Spar area. Pebbles 50% rounded shale Minor Fe staining on pebbles	23/06/94	-5	0.6	0.91
941112	Spar area. Pebbles 50% sub-angular Fe-stained shale and gossan.	23/06/94	-5	0.1	1.11
941113	Spar area. Pebbles 20% angular and rounded.	23/06/94	-5	1.7	1.01
941114	Field duplicate 941112	23/06/94	-5	-0.1	0.99
941115	Spar area. Pebbles 50% sub-angular shale & ferricrete.	23/06/94	7	7.9	1.2
941116	Spar area. Pebbles 20% sub-rounded shale. Faint white mottles on clay.	23/06/94	-5	2.1	1.01
941117	Spar area. Pebbles 20% sub angular ferricrete and shale. Fe-oxide cement.	23/06/94	-5	-0.1	0.73
941118	Spar area. Pebbles 50% sub angular shale.	23/06/94	-5	-0.1	0.62
941119	Spar area. Pebbles 5% angular-ferricrete.	23/06/94	-5	2.2	0.14
941122	Spar area. Pebbles 60% angular shale with abundant Fe-oxide.	24/06/94	-5	0.6	0.64
941123	Spar area. Pebbles 80% angular-banded ferricrete.	24/06/94	-5	0.4	0.3
941124	Spar area. Pebbles angular.	24/06/94	-5	0.2	0.19
941125	Spar area. Pebbles 90% sub-rounded shale.	24/06/94	-5	0.6	0.57
941126	Spar area. Fe hydroxide precipitate.	24/06/94	-5	1.2	0.01

ID	REMARKS	DATE	Ag ⁽¹⁾	Ag ⁽²⁾	Al ⁽²⁾
941131	Spar area. Fresh Fe hydroxide coating logs and vegetation.	24/06/94	13	0.6	0.31
941132	Spar area. Fresh Fe hydroxide around spring.	24/06/94	-5	-0.1	0.02
941133	Spar area. Fe hydroxide precipitate from small pool.	24/06/94	-5	0.2	0.02
941134	Spar area. Yellow to brown gelatinous clay from channel.	24/06/94	-5	0.4	0.02
941135	Spar area. Soil from 5 cm deep.	24/06/94	-5	1.7	0.09
941136	Spar area. Shale.	24/06/94	-5	1.7	0.19
941137	Spar area. Sand-silt and Fe-oxide cement.	24/06/94	-5	1	0.44
941202	Saint area. Fresh red-yellow gelatinous Fe precipitate 1 m from spring.	27/06/94	-5	0.5	0.03
941203	Saint area. Fresh yellow-brown Fe hydroxide 50 m down slope from spring on grey soil.	27/06/94	-5	-0.1	0.02
941204	Saint area. Yellow-brown, 80%clay/silt textured soil from area of previously active spring.	27/06/94	-5	0.5	0.09
941205	Saint area. Brown-yellow precipitate coating plant material	27/06/94	-5	-0.1	0.02
941206	Saint area. Soil from 20 cm deep.	27/06/94	-5	-0.1	0.04
941207	Saint area. Fresh colloidal Fe hydroxide precipitate.	27/06/94	-5	0.1	0.06
941208	Saint area. Hard, rippled, dark brown to black Fe-oxide.	27/06/94	-5	-0.1	0.02
941209	saint area. Yellow-brown water saturated sand, silt/clay mixture.	27/06/94	-5	0.6	0.21
941210	Saint area. Yellow-brown clay textured precipitate coating organic debris on edge of spring pool.	27/06/94	-5	0.4	0.08
941211	Saint area. Brown-black textured precipitate with terraced surface texture from flank of Fe-spring mound.	27/06/94	-5	0.3	0.09
941212	Saint area. Granular sandy red-brown oxide at 2-5 cm below surface above 1 m of water saturated soil.	27/06/94	-5	0.1	0.03
941213	Saint area. Brown-black sandy textured Fe-oxide material from 20-30 depth below surface.	27/06/94	-5	0.1	0.01
941214	Saint area. Yellow-red, clay textured precipitate by spring. Minor 'mature' Fe oxide mixed with sample.	27/06/94	-5	0.2	0.02
941215	Saint area. Light brown-red, silt clay textured fresh Fe precipitate 1 cm thick coating dark grey till or colluvium.	27/06/94	-5	0.6	0.1
941216	Saint area. Fresh terraced Fe-oxide coating surface of shale outcrop.	27/06/94	-5	0.4	1.66
941217	Saint area. Granular Fe-oxide coating on outcrop. No spring.	27/06/94	-5	-0.1	1.1
941219	Saint area. Fe-oxide on float in stream bed and terraced Fe precipitate from flank of spring mound.	27/06/94	-5	-0.1	0.04
941220	Saint area. Iron precipitate around spring.	27/06/94	-5	0.3	0.05
941302	Bear soil line 1. Pebbles 80%angular shale.	29/06/94	-5	1	0.61
941303	Bear soil line 1. Pebbles 80%angular shale.	29/06/94	-5	0.5	0.55
941304	Bear soil line 1. Pebbles 80%angular shale.	29/06/94	-5	0.8	0.5
941305	Bear soil line 1. Pebbles 40% angular shale and minor quartz.	29/06/94	-5	0.9	0.61
941306	Field duplicate sample 941305.	29/06/94	-5	0.8	0.61
941307	Bear soil line 1. Pebbles 30% ang-prismoidal shale ferricrete.	29/06/94	-5	0.9	0.49
941308	Bear soil line 1. Pebbles 50% ang/pris shale.	29/06/94	-5	0.4	0.56
941309	Bear soil line 1. Pebbles 50% sub ang pris shale.	29/06/94	-5	0.5	0.48
941310	Bear soil line 1. Pebbles 50% angular to sub-angular shale.	29/06/94	-5	0.1	0.57
941311	Bear soil line 1. Pebbles 30% angulat to sub-angular coarse clastic sediment and minor shale.	29/06/94	-5	0.2	0.4
941312	Bear soil line 1. Pebbles 60-70% angular shale.	29/06/94	-5	0.9	0.98
941313	Bear soil line 1. Pebbles 80% angular.	29/06/94	-5	1.2	0.48
941314	Bear soil line 1. Pebbles 80-90% sub-angular.	29/06/94	-5	1.2	0.52
941315	Bear soil line 1. Pebbles 80% sub-angular shale-varnished appearance. Fines appear washed out.	29/06/94	-5	2.7	0.95
941317	Bear soil line 1. Pebbles 60% sub-angular shale. Fines more abundant than 941317.	29/06/94	-5	0.7	0.91
941318	Bear soil line 1. Mainly pebbles and cobbles	29/06/94	-5	0.6	0.75
941319	Bear soil line 2. Pebbles 80% sub-angular. No shale.	30/06/94	-5	0.8	0.54
941320	Bear soil line 2. Pebbles 60-70% Sub angular, dark grey sandstone.	30/06/94	-5	0.3	0.45
941322	Bear soil line 2. Pebbles 50% sub-angular light-grey shale.	30/06/94	-5	0.2	0.69
941323	Bear soil line 2. Pebbles 50% sub-rounded.	30/06/94	-5	0.4	0.48
941324	Bear soil line 2. Pebbles 30% sub-angular.	30/06/94	-5	0.2	0.44
941326	Bear soil line 2. Pebbles 20% sub-angular.	30/06/94	-5	0.2	0.59
941327	Bear soil line 2. Pebbles 20% sub-rounded.	30/06/94	-5	0.7	0.84
941328	Bear soil line 2. Pebbles 50% sub angular.	30/06/94	10	7.6	0.57
941329	Bear soil line 2. Pebbles 40% sub-angular shale. Sample from barite frost boil-kill zone.	30/06/94	31	30.2	0.46
941330	Bear soil line 2. Pebbles 50% ang shale and barite.	30/06/94	-5	2.4	0.22
941331	Bear soil line 2. Pebbles 50% angular.	30/06/94	21	15.3	0.11
941332	Bear soil line 2. Pebbles 50% sub angular shale.	30/06/94	-5	0.7	0.4
941333	Bear soil line 2. Pebbles 30% sub-angular ferricrete.	30/06/94	-5	3.7	0.87
941334	Bear soil line 2. Pebbles 30% sub-angular ferricrete & shale.	30/06/94	-5	1.2	0.42
941402	Driftpile area profile. Pebbles 80% sub-angular shale.	01/07/94	-5	1.7	1.32
941403	Driftpile area profile. Pebbles 80% su-rounded. Fines washed from sediment.	01/07/94	-5	0.8	0.84
941404	Driftpile area profile. Pebbles 50% sub-angular. Light brown sandy layer below sample.	01/07/94	-5	0.8	0.79
941405	Driftpile area profile. Pebbles 70% sub-rounded shale & ferricrete.	01/07/94	-5	0.6	0.53
941406	Driftpile area profile. Hard Fe-oxide layer.	01/07/94	-5	0.5	0.46
941407	Driftpile area profile. Pebbles 10%	01/07/94	-5	0.3	0.56
941408	Driftpile area profile. Pebbles 40-50% sub-angular.	01/07/94	-5	0.2	0.49
941409	Driftpile area profile. Pebbles 50% ferricrete.	01/07/94	-5	0.3	0.37
941410	Driftpile area profile. Pebbles 60-70% sub-rounded.	01/07/94	-5	0.3	0.27

Notes:

Samples sieved at Geological Survey Branch Laboratory, Victoria to -230 mesh

2 = aqua regia digestion - inductively coupled plasma emission spectroscopy at ACME Analytical, Vancouver.

1 = Instrumental neutron activation analysis at Activation Laboratories, Ancaster, Ontario.

Appendix C - Rock Geochemical data

MAP	ID	UTMZ	UTME	UTMN	TYPE	DESCRIPTION
94F/13	945002	10	334950	6427730	O	Matrix from mature ferricrete.
94F/13	945003	10	338260	6427900	O	Broken ferricrete slabs from surface.
94F/13	945004	10	338195	6428000	O	Ferricrete sample from hard cemented layer 5-10 below surface.
94F/13	945005	10	338198	6428005	O	Ferricrete slabs from surface.
94F/13	945006	10	338205	6428005	O	Ferricrete slabs from surface.
94F/13	945007	10	338215	6428010	S	Medium grey weathering shale with minor limonitic staining.
94F/13	945008	10	338320	6427895	S	Medium-grey coloured weathered shale.
94F/13	945010	10	337825	6429530	O	Light grey iron stained shale. Scattered pyrite cubes.
94F/13	945011	10	337865	6429570	O	Banded ferricrete from dry creek bed.
94F/13	945012	10	337865	6429570	O	Matrix of mature ferricrete.
94F/13	945013	10	338070	6429570	O	Ferricrete crusts from surface of kill zone.
94F/13	945014	10	338100	6429710	O	Ferricrete from creek bed.
94F/13	945015	10	338030	6429630	O	Possibly smithsonite slabs on surface of kill zone.
94F/13	945017	10	335000	6428050	O	Very recently deposited banded cold spring iron oxide deposit .
94F/13	945018	10	335280	6428000	O	Matrix of mature ferricrete from W bank of creek.
94F/13	945019	10	335580	6427630	S	Rusty weathering black shale from W bank of creek
94F/13	945020	10	334850	6427620	O	Sample of mature ferricrete.
94F/13	945022	10	334860	6427620	S	Sample from grey shale from W bank of creek
94F/13	945023	10	334980	6427420	O	Matrix of mature ferricrete from large outcrop east of creek.
94F/13	945024	10	335060	6427170	O	Matrix of mature ferricrete from large outcrop east of creek.
94K/4	945026	10	323580	6446450	O	Sample of "Rippled -terraced" laminated iron oxide from surface.
94K/4	945027	10	323580	6446450	O	Granular to sandy textured red-brown iron oxide from surface.
94K/4	945029	10	323320	6446900	O	Pebble sized angular granular iron oxide clasts from surface.
94K/4	945030	10	323310	6446905	O	Pebble sized angular granular iron oxide clasts from surface 20m S from 945029.
94K/4	945031	10	323300	6446910	S	Dark grey graphitic shale from limb of small fold. Minor pyrite. Outcrop W of creek.
94K/4	945032	10	324140	6445970	O	Matrix of mature ferricrete from large outcrop on Sside of creek.
94K/4	945033	10	324210	6445930	O	Matrix of mature ferricrete from large outcrop on Sside of creek 20 m W of 945032.
94K/4	945034	10	324280	6445890	O	Matrix of mature ferricrete from large outcrop on Sside of creek 50 m W of 945032.
94K/4	945035	10	324330	6445710	O	Ferricrete from east side of creek.
94K/4	945036	10	324210	6445740	O	Granular iron oxide.
94F/13	945042	10	334535	6428010	S	Light grey weathering. Medium to dark grey silty shale. Minor limonite on cleavages.
94F/13	945043	10	334540	6428030	S	Light grey weathering. Medium to dark grey silty shale. Minor limonite on cleavages.
94F/13	945044	10	334980	6427910	S	Grey weathering, cherty shale. Minor limonite staining and quartz veining.
94F/13	945045	10	334980	6428000	B	Float from surface of large barite kill zone.
94F/13	945046	10	334885	6428100	O	Ferricrete from base of pit.
94K/4	945047	10	328700	6440880	O	Ferricrete sample.
94K/4	945048	10	328710	6440880	O	Ferricrete crusts from surface of upper part of kill zone
94K/4	945049	10	328710	6440860	O	Ferricrete crusts from surface of lower part of kill zone
94F/13	945050	10	337600	6429805	O	Friable ferricrete from surface of shale talus fan 200 m north from 943070)
94F/13	945051	10	337600	6429805	O	Sample from slabs of dusky-red banded ferricrete 10 m from 945050.
94F/13	945052	10	337600	6429805	O	Sample of yellow-brown "veined" ferricrete from slabs scattered on talus 30 noth of 945050.
94F/13	945053	10	333390	6430240	O	Granular ferricrete from surface of dry kill zone.
94F/13	945054	10	334490	6429360	S	Rusty weathering grey laminated silty shale outcrop 100m from ridge crest.
94F/13	945055	10	334485	6429355	S	Light grey weathering, blebbly baritic shale from outcrop. Minor pyrite and limonite.
94F/13	945056	10	334485	6429335	S	Dark grey blebbly shale from outcrop . Moderate graphite and minor Minor limonite.
94F/13	945057	10	334490	6429350	S	Dark grey blebbly shale from outcrop 10 north from 945056. Moderate graphite and minor limonite.
94F/13	945058	10	334485	6429348	S	Grey weathering, silty, carbonaceous shale.
94F/13	945060	10	333890	6430485	S	Tightly folded, graphitic black shale from outcrop.
94F/13	945062	10	333890	6430490	S	Tightly folded, graphitic black shale from outcrop.
94F/13	945063	10	334485	6429648	S	Grey weathering, dark grey graphitic shale.
94F/13	945064	10	333905	6431530	S	Light grey to brown weathering, medium grey silty shale 1 m above spring.
94F/13	945065	10	333900	6431525	S	Tightly folded light grey shale from OC 100m N from 945064. Minor Qtz veins.
94F/13	945066	10	333900	6431525	S	Ribbon-banded baritic shale 1-2 m north of 945065.
94F/13	945067	10	333850	6431610	S	Medium grey rusty mottled weathering dark grey shale cut by sheeted quartz veins.
94F/13	945068	10	333925	6431392	S	Medium grey shale from outcrop 1-2m east of spring.
94F/13	945069	10	333340	6432180	O	Friable red-brown ferricrete from slabs on surface of kill zone.
94F/13	945070	10	332360	6433000	S	Rusty, limonite stained, pyritic shale grey shale interbed in oxide sample 945077.
94F/13	945071	10	332360	6433000	S	Grey shale.
94L/1	945073	10	333200	6438045	O	Friable, dark red-black iron oxide from outcrop. Layer dips 10-15°W at 10-20 cm depth.
94L/1	945074	10	333150	6438040	G	Drift at 100 cm depth at base of profile.
94L/1	945075	10	333150	6438040	G	Medium brown sand 1-2 cm above 945074 at 95-96 cm depth.
94L/1	945076	10	333150	6438040	O	Laminated iron oxide layer at 92-94 cm depth.
94L/1	945077	10	333150	6438040	O	Laminated iron oxide containing wood at 88-90 cm depth.

Open File 2001-07
Appendix C - Rock Geochemical data

MAP	ID	UTMZ	UTME	UTMN	TYPE	DESCRIPTION
94L/1	945078	10	333150	6438040	G	Yellow to brown coloured massive sand with small discoid pebbles at 60-64 cm depth.
94L/1	945079	10	333150	6438040	O	Laminated iron oxide at 50-54 cm depth.
94L/1	945080	10	333150	6438040	O	Laminated iron oxide at 20-24 cm depth.
94L/1	945082	10	333150	6438040	O	Surface iron oxide deposits.
94L/1	945083	10	332790	6438120	O	Iron oxide crusts from surface of outcrop.
94L/1	945084	10	328170	6439830	O	Mature ferricrete from large slabs on kill zone.
94L/1	945085	10	328165	6439830	S	Light grey shale from outcrop at edge of road.

APPENDIX D - STREAM AND MOSS MAT FIELD AND ANALYTICAL DATA

Reference Guide to Field Observations

MAP	1:50 000 NTS Map Sheet Number		BNK PPT Bank Precipitate:
ID	Sample ID Number		N None (otherwise, = SED COL)
UTMZ	UTM Zone		CHL BD Channel Bed:
UTME	UTM East Coordinate (NAD 83)		S Coarse sand - gravel B Boulders
UTMN	UTM North Coordinate (NAD 83)		F Fine sand - clay O Organic matter
LAT	Latitude (decimal degrees)		CHL PTN Channel Pattern:
LONG	Longitude (decimal degrees)		S Shoots and pools M Meandering
STN	Replicate Sample Status :		B Braided D Disturbed
	0 - Routine Sample: 1 - 1st Field Duplicate: 2 - 2nd Field Duplicate		ELEV Sample site elevation above sea level (metres).
MED	Sample Medium :		PHY Physiography :
	1 Stream Sediment 7 Moss mat sediment		Y Youthful Mts M Mature Mts. L Lowland Plain H Hilly Undulating
WAT COL	Water Colour :		DRN Drainage Pattern :
	0 Colourless 2 White Cloudy 1 Brown Clear 3 Brown Cloudy		D Dendritic T Herringbone
FLW	Water Flow Rate :		TYP Stream Type :
	1 Slow 3 Fast 2 Moderate 4 Torrent		P Permanent S Seasonal
SED COL	Sediment Colour :		ODR Stream Order :
	R Red W White-Buff G Grey-Blue O Olive-Green T Tan-Brown B Black		1 Primary 3 Tertiary 2 Secondary 4 Quaternary
SED PPT	Sediment Precipitate:		SRC Stream Source :
	N None (otherwise = SED COL)		M Melt Water G Groundwater
CON	Site Contamination:		HGTH Height of moss (m) above water level
	N None D Domestic P Possible		COLR Moss colour. L - Light D - Dark
COMP	Sediment Composition, Estimate of Sand - Fines - Organic Content :		HLTH Moss health: A Alive D Dead
	0 Absent 1 Minor (<1/3 of total) 2 Moderate (1/3 to 2/3 of total) 3 Major (>2/3 of total)		HOST Most growth host :
WDTH	Stream Width (metres)		1 Rock - competent 3 Log - competent 2 Rock - incompetent 4 Log - incompetent
DPTH	Stream Depth (centimetres)		THCK Moss mat thickness (cm)
BNK	Bank Composition :		DATE Sample Collection Date (day/month)
	U Unknown C Colluvium A Alluvium R Rock G Glacial outwash O Organic T Till S Scree, talus		METHOD CODE ¹ - INAA: ² - ICPES

APPENDIX E - SEQUENTIAL EXTRACTION ANALYTICAL DATA

Reference Guide to Data

ID	Sample ID Number
STN	Replicate Sample Status :
	0 - Routine Sample: 1 - 1st Field
	Duplicate: 2 - 2nd Field Duplicate
M-1	Element extracted with 0.25 M hydroxylamine hydrochloride and analysed by ICPES
M-2	Element extracted with 1 M hydroxylamine hydrochloride and analysed by ICPES
M-3	Element extracted with concentrated hydrochloric-nitric-perchloric-hydrofluoric acid and analysed by ICPES
